Integrative Physiology

Essential Role of Bone Marrow for Microvascular Endothelial and Metabolic Functions in Mice

Sota Nakajima, Junko Ohashi, Ayuko Sawada, Kazuki Noda, Yoshihiro Fukumoto, Hiroaki Shimokawa

Rationale: We have previously demonstrated that the importance of endothelium-derived hyperpolarizing factor (EDHF) increases as the vessel size decreases and that endothelium-derived hydrogen peroxide (H₂O₂) is an EDHF in animals and humans, for which endothelial nitric oxide synthase (eNOS) is the major source. Recent studies have suggested the important role of the bone marrow (BM) in modulating cardiovascular and metabolic functions.

Objective: We aimed to examine whether BM plays a role in modulating microvascular endothelial and metabolic functions in mice, and if so, to elucidate the mechanisms involved.

Methods and Results: Male eNOS⁻/⁻ mice were transplanted with BM cells from wild-type (WT) or eNOS⁻/⁻ mice and were maintained for 6 weeks. Endothelium-dependent relaxations and hyperpolarizations of mesenteric arteries to acetylcholine were reduced in eNOS⁻/⁻ mice and were markedly improved when transplanted with WT-BM but not with eNOS⁻/⁻-BM. The enhanced component of endothelial-dependent relaxations was abolished by catalase, indicating that the improved responses were mediated by H₂O₂. In contrast, no such beneficial effect was noted in the aorta. Reduced plasma adiponectin levels and impaired glucose tolerance in eNOS⁻/⁻ mice were also improved by WT-BM transplantation. Neuronal nitric oxide synthase (nNOS) in mesenteric arteries of eNOS⁻/⁻ mice was significantly upregulated only when transplanted with WT-BM. Importantly, the beneficial effects of WT-BM transplantation were absent in eNOS⁻/⁻/adiponectin⁻/⁻ or eNOS⁻/⁻/nNOS⁻/⁻ mice.

Conclusions: These results provide the first evidence that BM plays an important role in modulating microvascular endothelial and metabolic functions, for which adiponectin and nNOS may be involved. (Circ Res. 2012;111:87-96.)

Key Words: nitric oxide synthases ■ endothelium-derived hyperpolarizing factor ■ bone marrow ■ adiponectin

The endothelium plays an important role in maintaining vascular homeostasis by synthesizing and releasing several vasodilators, including prostacyclin, nitric oxide (NO), and endothelium-derived hyperpolarizing factor (EDHF). It is widely accepted that EDHF plays an important role in modulating vascular tone, especially in microvessels. In addition, endothelial function is impaired by hypertension, glucose intolerance, insulin resistance, dyslipidemia, obesity, and metabolic syndrome. We have previously demonstrated that endothelium-derived hydrogen peroxide (H₂O₂) is an EDHF in mouse and human mesenteric arteries and porcine coronary microvessels. Other investigators confirmed the importance of H₂O₂ as an EDHF in human and canine coronary microvessels and porcine pial arteries. We also have demonstrated that endothelial nitric oxide synthase (eNOS) is a major source of EDHF/H₂O₂, where copper, zinc-superoxide dismutase plays an important role to dismutate eNOS-derived superoxide anions to EDHF/H₂O₂ and that endothelial NOSs system plays different roles depending on the vessel size, serving as the NO-generating system in large arteries and as the EDHF/H₂O₂-generating system in microvessels in mice. Furthermore, we have recently demonstrated that when the all 3 NOSs [eNOS, neuronal NOS (nNOS), and inducible NOS (iNOS)] are genetically deleted in mice, acute myocardial infarction develops spontaneously associated with unique phenotypes that resemble metabolic syndrome in humans, including glucose intolerance, hypertension, dyslipidemia, and visceral obesity. These results indicate the close coupling between microvascular endothelial functions and metabolic disorders, although the detailed mechanisms remain to be elucidated.
It has been recently demonstrated that some blood cells [eg, neutrophils, macrophages, and endothelial progenitor cells (EPCs)] are involved in the development of cardiovascular diseases, including atherosclerosis, cardiovascular events, vasospastic angina, and angiogenesis. However, measured by tail-cuff method.

After blocking of endogenous biotin and avidin binding sites, sections were subjected to immunohistochemical staining overnight at 4°C with an anti-F4/80 monoclonal antibody. Immune complexes were detected with biotinylated secondary antibodies, horseradish peroxidase–conjugated streptavidin and the peroxidase substrate diaminobenzidine.

**Statistical Analysis**

Statistical analysis was performed with JMP 9.0 (SAS Institute Inc, Cary, NC). Results are shown as mean±SEM. Dose-response curves were analyzed by 2-way ANOVA followed by Tukey HSD test for multiple comparisons. Other variables were analyzed by Student’s t test or 1-way ANOVA followed by Tukey HSD test for multiple comparisons. *P*<0.05 was considered to be statistically significant.

**Results**

Chimerism in Transplanted Mice

Chimerism in transplanted eNOS−/− mice was analyzed by the percentage of EGFP+ nucleated blood cells found in peripheral blood at 5 weeks after BM transplantation. All animals showed >85% chimerism (WT-BM, 90.2±0.6%; eNOS−/−-BM, 87.3±0.3%, n=5–7).

**Body Weight, Systolic Blood Pressure, and Blood Cell Counts**

In the present study, we examined 4 groups of mice, including sham-transplanted (control) WT and eNOS−/− mice and eNOS−/− mice transplanted with WT-BM or eNOS−/−-BM (Online Table I). At baseline, body weight was greater in the 3 eNOS−/− groups than in WT. At 6 weeks after BM or vehicle injection, there was no significant difference in body weight among the 4 groups. Systolic blood pressure was significantly higher in the 3 eNOS−/− groups compared with WT throughout the experimental period (Online Table I). At 5 weeks after BM or vehicle injection, control eNOS−/− mice had higher white and red blood cell counts, increased hemoglobin levels, and decreased platelet count compared with...
control WT. The increased white and red cell counts and hemoglobin levels were normalized by transplantation with WT-BM or eNOS<sup>−/−</sup>-BM, whereas platelet count was unchanged (Online Table I).

**Endothelium-Dependent Relaxations and Hyperpolarizations**

In isolated mesenteric arteries of control WT mice, ACh elicited concentration-dependent relaxations, which were resistant to indomethacin (vasodilator PGs component) or indomethacin plus L-NNA (NO component), but was highly sensitive to the combination of apamin and charybdotoxin in the presence of indomethacin and L-NNA (EDHF component) (Figure 1A). In mesenteric arteries of control eNOS<sup>−/−</sup> mice, endothelium-dependent, EDHF-mediated relaxations to ACh were markedly attenuated compared with those of WT mice (Figure 1B), a consistent finding with our previous studies. Transplantation with WT-BM but not that with eNOS<sup>−/−</sup>-BM markedly improved the EDHF-mediated relaxations (Figure 1C and 1D). The enhanced component of EDHF-mediated relaxations was abolished in endothelium-denuded mesenteric artery (Online Figure I, A). In addition, this enhanced component was markedly inhibited by catalase, indicating that the improved responses were mediated by endothelium-derived H<sub>2</sub>O<sub>2</sub> (Figure 1E). Similarly, EDHF-mediated relaxations in WT mice mesenteric arteries were markedly inhibited by catalase, whereas NO-mediated relaxations in WT mice aorta were not affected by catalase (Online Figure II, A and B). Absolute values of contractions of mesenteric artery to prostaglandin F<sub>2α</sub> were comparable among all the groups (Online Table II).

Electrophysiological recordings of membrane potentials with the microelectrode technique in mesenteric arteries demonstrated that endothelium-dependent hyperpolarizations to ACh (10<sup>−5</sup> mol/L) were significantly reduced in eNOS<sup>−/−</sup>-mice compared with WT mice and were significantly improved with WT-BM transplantation but not with eNOS<sup>−/−</sup>-BM transplantation (Figure 1F).

In contrast to mesenteric arteries, endothelium-dependent relaxations of the aorta to ACh were mainly mediated by NO in WT mice as L-NNA abolished the responses (Figure 2A) and were totally absent in eNOS<sup>−/−</sup> mice (Figure 2B). No beneficial effect of BM transplantation with WT-BM or eNOS<sup>−/−</sup>-BM was noted in the aorta of eNOS<sup>−/−</sup> mice (Figure 2C and 2D).

**Endothelium-Independent Relaxations**

There was no significant difference in endothelium-independent relaxations to NS1619 [an opener of calcium-activated potassium (K<sub>Ca</sub>) channels] or sodium nitroprusside (SNP) in mesenteric arteries and the aorta between WT-BM and eNOS<sup>−/−</sup>-BM mice (Online Figure III, A through D). In addition, there was no significant difference in endothelium-independent relaxations of mesenteric artery to SNP regardless of the presence or absence of the endothelium in WT-BM eNOS<sup>−/−</sup> mice (Online Figure I, B). Furthermore, the relaxations to NS1619 were unaltered by catalase in mesenteric arteries when transplanted with WT-BM (Online Figure III, A), and the relaxations to SNP were unaltered by catalase in WT mouse mesenteric arteries and aorta (Online Figure II, C and D).

**Immunostaining of Mesenteric Artery and Aorta in eNOS<sup>−/−</sup> Mice**

Immunofluorescence staining was performed in mesenteric arteries and the aorta of GFP<sup>+</sup> WT-BM eNOS<sup>−/−</sup>-mice and GFP<sup>+</sup> eNOS<sup>−/−</sup>-BM eNOS<sup>−/−</sup>-mice. We observed a small number of GFP-positive BM-derived cells in the adventitia of mesenteric artery (WT-BM, 0.6±0.6; eNOS<sup>−/−</sup>-BM, 0.8±0.2, n=5 each, not statistically significant) but not in the intima or media of mesenteric artery or in the aorta (Online Figure IV, A). Immunohistochemical staining was performed in mesen-
Flow Cytometry Analysis to Assess EPC
Flow cytometry analysis was performed to examine the number of circulating EPC defined as Sca-1+/Flk-1+ mononuclear cells (Online Figure VI, A and B). There was no significant difference in the EPC number among WT, WT-BM, and eNOS⁻/⁻-BM eNOS⁻/⁻ mice (Online Figure VI, C).

Glucose Tolerance Tests and Plasma Levels of Lipids
Glucose tolerance test was performed in all 4 groups at 5 weeks after BM or vehicle injection. Although plasma glucose levels were comparable at baseline and 15 minutes after glucose injection in all groups, the levels were significantly higher at the 30 and 60 minutes in control eNOS⁻/⁻ mice compared with control WT mice. The impaired glucose tolerance in eNOS⁻/⁻ mice was markedly improved with WT-BM transplantation but not with eNOS⁻/⁻-BM transplantation. Results are expressed as mean±SEM. *P<0.05 versus control WT, †P<0.05 versus control eNOS⁻/⁻, ‡P<0.05 versus eNOS⁻/⁻-BM eNOS⁻/⁻.

Visceral Fat and Plasma Levels of Adiponectin
The size of epididymal white adipose cells, one of the representative visceral fats, was significantly larger in control eNOS⁻/⁻ mice than in control WT mice and was diminished when transplanted with WT-BM but not with eNOS⁻/⁻-BM transplantation (Figure 4A and 4B). We also performed immunostaining for the F4/80 antigen, a specific marker for mature macrophages, and calculated the percentage of F4/80-expressing cells in the epididymal white adipose tissue. The percentage was significantly higher in eNOS⁻/⁻ mice than in WT mice, and aggregates of F4/80-expressing cells were noted in control eNOS⁻/⁻ but not in control WT mice (Figure 4A through 4C). The percentage was significantly reduced with WT-BM transplantation but not with eNOS⁻/⁻-BM transplantation (Figure 4A and 4C). Plasma adiponectin level was significantly reduced in eNOS⁻/⁻ mice compared with WT mice and was significantly improved with WT-BM transplantation but not with eNOS⁻/⁻-BM transplantation (Figure 4D).

Experiments With eNOS⁻/⁻/Adiponectin⁻/⁻ Mice
We also performed the experiments with eNOS⁻/⁻/APN⁻/⁻ mice with or without WT-BM transplantation. Unlike eNOS⁻/⁻ mice, WT-BM transplantation had no beneficial effects on endothelium-dependent relaxations of mesenteric arteries of eNOS⁻/⁻/APN⁻/⁻ mice (Figure 5A and 5B). Interestingly, WT-BM transplantation to eNOS⁻/⁻/APN⁻/⁻
mice significantly enhanced indomethacin-sensitive endothelium-dependent relaxations, suggesting an upregulation of vasodilator prostaglandins (Figure 5A and 5B). Endothelium-independent relaxations of mesenteric arteries to NS1619 or SNP were unaltered with WT-BM transplantation in eNOS−/−/APN−/− mice (Online Figure VII). The impaired glucose tolerance in eNOS−/−/APN−/− mice was also unaltered with WT-BM transplantation (Figure 5C). Plasma adiponectin was not detected in control eNOS−/−/APN−/− or WT-BM eNOS−/−/APN−/− (Figure 5D).
Protein Expression of eNOS and nNOS

As expected, eNOS protein expression of mesenteric arteries was absent in eNOS+/− mice transplanted with WT-BM or eNOS+/−-BM (Figure 6A). In contrast, nNOS protein expression of mesenteric arteries was significantly greater in eNOS+/− mice transplanted with WT-BM compared with those with eNOS+/−-BM, whereas it was comparable in the aorta (Figure 6B). In eNOS−/−/APN−/− mice, WT-BM transplantation did not alter nNOS protein expression of mesenteric arteries (Figure 6C).

Experiments With n/eNOS+/− Mice

We also performed the experiments with n/eNOS+/− mice with or without WT-BM transplantation. Unlike eNOS+/− mice, WT-BM transplantsations caused no beneficial effects on endothelium-dependent relaxations of mesenteric arteries (Figure 7A and 7B). In contrast, WT-BM transplantation to n/eNOS+/− mice tended to enhance indomethacin-sensitive endothelium-dependent relaxations, suggesting an upregulation of vasodilator prostaglandins (Figure 7A and 7B). Endothelium-independent relaxations of mesenteric arteries to NS1619 or SNP were unaltered with WT-BM transplantation in n/eNOS−/− mice (Online Figure VIII, A and B).

Effect of Adiponectin Treatment to eNOS−/− Mice

We intraperitoneally injected recombinant mouse adiponectin (500 μg/kg BW) or PBS into male eNOS−/− mice at the age of 13 weeks once daily for 7 days. Treatment with adiponectin significantly improved EDHF-mediated relaxations in mesenteric arteries compared with PBS-treated mice (Figure 8A and 8B). In contrast, the adiponectin treatment had no significant effects in the aorta (Figure 8C and 8D). Endothelium-independent relaxations of mesenteric arteries to NS1619 or SNP were comparable between adiponectin-treated and PBS-treated groups (Online Figure IX).

Discussion

The major findings of the present study were as follows: (1) eNOS−/− mice were characterized by absence of NO-mediated relaxations and reduced EDHF-mediated relaxations associated with impaired glucose tolerance and dyslipidemia, (2) WT-BM transplantation to eNOS−/− mice almost normalized EDHF-mediated endothelium-dependent relaxations of mesenteric arteries and glucose tolerance, (3) the enhancing effects of WT-BM transplantation on the EDHF-mediated responses were mediated primarily by endothelium-derived H2O2, and (4) the beneficial effects of WT-BM transplantation on EDHF-mediated relaxations were reduced in untreated eNOS−/−/nNOS−/− mice. B, WT-BM transplantation had no effect on EDHF-mediated relaxations to ACh of mesenteric arteries from eNOS−/−/nNOS−/− mice. Results are expressed as mean±SEM.
transplantation on EDHF-mediated responses in eNOS−/− mice were mediated by adiponectin and nNOS. To the best of our knowledge, this is the first study that demonstrates that BM plays an essential role for microvascular endothelial and metabolic functions, for which adiponectin and nNOS are substantially involved.

Effects of WT-BM Transplantation
In eNOS−/− mice, WT-BM transplantation markedly improved and almost normalized EDHF-mediated and endothelium-dependent relaxations, whereas eNOS−/−/BM transplantation was without the effects. We have previously demonstrated that EDHF-mediated relaxations and hyperpolarizations of mesenteric arteries are markedly reduced (but not absent) in eNOS−/− mice, where the remaining 2 NOSs (nNOS and iNOS) play a compensatory role.10,20 It is known that eNOS generates superoxide anions under normal conditions from reductase domain, and only when pathologically uncoupled (eg, depletion of BH4 and/or L-arginine) it generates superoxide anions from oxidase domain and that L-arginine analogues inhibits the latter process alone.35 We have previously reported that H2O2 as an EDHF is generated from reductase domain, and only when pathologically uncoupled that eNOS generates superoxide anions under normal conditions.35 We have previously demonstrated that BM-derived cells do not differentiate into vascular endothelial or smooth muscle cells in mice.27–30 In the present study, we also were unable to observe the presence of BM-derived cells in the vascular wall of eNOS−/− mice transplanted with GFP-positive BM or eNOS protein expression in mesenteric arteries of eNOS−/− mice transplanted with WT-BM. Furthermore, WT-BM transplantation did not improve endothelial-dependent relaxations of the aorta from eNOS−/− mice, although it markedly improved the responses of mesenteric arteries. Thus, we consider that the improvement of endothelium-dependent relaxations of mesenteric artery from eNOS−/− mice by WT-BM transplantation was mediated by humoral factor(s) but not by differentiation of EPCs or other BM-derived progenitor cells to endothelial cells.

Roles of Adiponectin
Adiponectin is an abundant plasma protein specifically secreted by adipocytes,41 playing an important role in the regulation of glucose and lipid metabolism.42 The serum levels of adiponectin are inversely correlated with the extent of visceral fat.43 Moreover, hypoadiponectinemia is associated with reduced endothelium-dependent dilatation in both diabetic and nondiabetic human subjects.44 We and others showed that eNOS−/− mice had low serum levels of adiponectin and hypertrophic visceral adipose cells.21,45 Interestingly, in the present study, WT-BM transplantation to eNOS−/− mice decreased the size of visceral adipose cells and increased plasma levels of adiponectin, whereas WT-BM transplantation had no effect on the adiponectin level in control eNOS−/−/APN−/− or WT-BM eNOS−/−/APN−/− mice. Furthermore, the F4/80 antigen, a marker for mature mouse macrophages, was greatly expressed in epididymal white adipose tissue of eNOS−/− mice compared with WT mice and WT-BM transplantation to eNOS−/− mice decreased these expressions. Obesity and metabolic syndrome are associated with macrophage infiltration in adipose tissue.46,47 Macrophage-specific expression of adiponectin suppresses the development of obesity and macrophage infiltration to adipose tissue and improved insulin sensitivity in mice.48 Transgenic mice expressing monocyte chemoattractant protein-1 (MCP-1) in the adipose tissue exhibit enhanced macrophage infiltration and insulin resistance, whereas in MCP-1−deficient mice, macrophage accumulation in the adipose tissue, insulin resistance, and hepatic steatosis are improved associated with increased serum levels of adiponectin.54 These results suggest the metabolic syndrome–like phenotypes of eNOS−/− mice is caused by reduced adiponectin levels and enhanced macrophage infiltration, both of which are related to reduced eNOS functions.

Roles of nNOS
Adiponectin promotes phosphorylation of AMP-activated protein kinase, protein kinase Akt/protein kinase B, and eNOS in HUVEC in vitro.49 The eNOS expression in the aorta from adiponectin−/− mice is decreased in vivo, whereas
adenovirus-mediated delivery of adiponectin increases eNOS expression in the aorta from KK-Ay mice (a mouse model for type 2 diabetes) and adiponectin−/− mice.50 These results indicate that adiponectin enhances eNOS expression and activity. In the present study, nNOS expression in mesenteric arteries was enhanced in eNOS−/− mice when transplanted with WT-BM but not with eNOS−/−/BM. nNOS is usually expressed in nerve tissues but is also constitutively expressed in endothelial cells as is eNOS.51 Especially when expression and activity of eNOS are reduced, nNOS (and iNOS) exerts compensatory effects.52,53 Indeed, EDHF-mediated and endothelium-dependent relaxations were totally absent only when all 3 NOSs were deleted in mice.20

To confirm our hypothesis on the roles of adiponectin and nNOS, we also performed experiments with eNOS−/−/APN−/− mice and eNOS−/−/nNOS−/− mice. In both mice, endothelium-dependent and EDHF-mediated relaxations of mesenteric arteries were reduced compared with control eNOS−/− mice. Importantly, unlike eNOS−/− mice, WT-BM transplantation failed to improve EDHF-mediated relaxations in those mice. Furthermore, the treatment with recombinant adiponectin improved EDHF-mediated relaxations in eNOS−/− mice as did WT-BM transplantation. In addition, in eNOS−/−/APN−/− mice, WT-BM transplantation enhanced relaxations mediated by vasodilator PGs. These results suggest that both adiponectin-dependent and adiponectin-independent mechanisms are involved in the effects of WT-BM transplantation in eNOS−/− mice.

Although it remains to be examined whether adiponectin also enhances the expression and activity of nNOS as in the case of eNOS, it is conceivable that increased adiponectin levels by WT-BM transplantation may upregulate nNOS in the endothelium of mesenteric arteries from eNOS−/− mice, enhancing endothelium-dependent and EDHF-mediated relaxations. Although the molecular mechanism of nNOS upregulation by adiponectin remains to be elucidated, it is conceivable that anti-inflammatory effects of adiponectin and those of eNOS-derived H2O2/EDHF may be involved.

**Study Limitations**

Several limitations should be mentioned for the present study. First, although we were able to elucidate the important roles of adiponectin and nNOS in the beneficial effects of WT-BM transplantation in eNOS−/− mice, the detailed molecular mechanisms remain to be elucidated. Second, it remains to be determined why WT-BM transplantation had no beneficial effects on endothelial function of the aorta. Third, although WT-BM transplantation improved EDHF-mediated relaxations in eNOS−/− mice, blood pressure was not improved. Several possibilities should be considered to explain this observation, including the limitation of tail-cuff method to measure blood pressure and the partial improvement of the responses as compared with genetic modulation.13 Fourth, in the present study, WT-BM transplantation improved (almost normalized) microvascular endothelial functions, glucose tolerance, lipid profiles, adiponectin levels, and macrophage infiltration in the visceral adipose tissue, the cause-result relationships among those changes remain to be established. In addition, the background underlying these changes (e.g., renin-angiotensin system and oxidative stress) remains to be examined.

**Clinical Implications**

The present study has important clinical implications. eNOS−/− mice are characterized by the phenotypes resembling metabolic syndrome in humans21,24,55 and thus could be regarded as an animal model of atherosclerosis and metabolic disorders. Since WT-BM transplantation almost normalized microvascular endothelial and metabolic functions, the present results suggest that BM function could be a new therapeutic target of cardiovascular and metabolic disorders. It remains to be examined in future studies what therapeutic options could improve BM functions in atherosclerotic animals models as well as patients with athero-metabolic disorders.

**Conclusions**

The present study provides the first evidence that BM plays an important role in modulating microvascular endothelial and metabolic functions, for which adiponectin and nNOS may be involved.

### Novelty and Significance

**What Is Known?**

- The endothelium plays an important role in vascular homeostasis by synthesizing and releasing vasodilator prostaglandins, nitric oxide, and endothelium-derived hyperpolarizing factor (EDHF).
- Endothelial nitric oxide synthases (eNOS)-derived hydrogen peroxide ($\text{H}_2\text{O}_2$) is a major source of EDHF in microvessels of animals and humans.
- Several leukocyte populations contribute to the pathogenesis of cardiovascular diseases.

**What New Information Does This Article Contribute?**

- Transplantation of wild-type bone marrow to eNOS-deficient mice improves endothelial vasodilator functions in small mesenteric arteries that are mediated by EDHF/$\text{H}_2\text{O}_2$ derived from neuronal NO synthase (nNOS).
- Wild-type bone marrow transplantation in eNOS-deficient mice improves glucose intolerance and dyslipidemia.
- These beneficial effects of wild-type bone marrow transplantation are mediated by adiponectin and nNOS as they are abolished in eNOS/adiponectin-deficient or eNOS/nNOS-deficient mice.

The endothelium plays an important role in maintaining vascular homeostasis by synthesizing and releasing endothelium-derived relaxing factors, including vasodilator prostaglandins, NO, and EDHF. The contribution of NO increases as the vessel size becomes larger, and, conversely, that of EDHF increases as the vessel size becomes smaller. Microvascular endothelial functions are closely linked to cardiovascular and metabolic diseases. In this study, we demonstrated that transplantation of wild-type bone marrow equals enhanced EDHF-mediated endothelial functions in eNOS-deficient mice through EDHF/$\text{H}_2\text{O}_2$ derived from nNOS. Moreover, transplantation of bone marrow from wild-type mice also improved glucose intolerance and dyslipidemia in eNOS-deficient mice. Importantly, the beneficial effects of wild-type bone marrow transplantation were abolished in eNOS/adiponectin- or eNOS/nNOS-deficient mice. Thus, the present findings provide new evidence that bone marrow plays an important role in modulating microvascular endothelial and metabolic functions in the organ network involving bone marrow, fat tissue, and blood vessels. We suggest that bone marrow functions could be a new therapeutic target in management of cardiovascular and metabolic disorders.

Detailed Methods

Animals and tissue preparation
The present study was reviewed and approved by the Committee on Ethics of Animal Experiments of Tohoku University. Male mice aged 8 weeks were used. The eNOS−/− mice were originally provided by P. Huang (Harvard Medical School, Boston, MA). The eNOS−/− mice were backcrossed to C57BL/6 mice over 10 generations. Thus, C57BL/6 mice were used as a WT control. We generated n/eNOS−/− mice by crossing nNOS−/− and eNOS−/− mice, as previously reported 1. eNOS−/−/APN−/− mice were generated by crossing eNOS−/− and APN−/− mice (Jackson Laboratory, Bar Harbor, ME, USA). Systolic blood pressure was measured by tail-cuff method (MK-2000, Muromachi). The animals were anesthetized with intraperitoneal pentobarbital (50 mg/kg), blood was collected from the heart using a plastic microsyringe, and small mesenteric arteries, aorta, and epididymal fat were excised to be used for the experiments.

BM transplantation
BM transplantation was performed as described previously 2. Briefly, recipient mice were lethally irradiated and received an intravenous injection of 5x10⁶ donor BM cells suspended in Ca- and Mg-free phosphate-buffered saline (PBS) with 3 % fetal bovine serum (FBS). After transplantation, the mice were placed on a regular chow diet for 6 weeks. We generated GFP-positive WT and GFP-positive eNOS−/− mice by crossing with transgenic mice ubiquitously expressing GFP 3. The chimeric rate was assessed by reconstitution with GFP+ BM cells by FACS analysis (FACSCanto II; BD).

Organ chamber experiments
Experiments were performed in 37°C Krebs solution bubbled with 95% O₂ and 5% CO₂. Isometric tension was recorded using isolated small mesenteric arteries (200-250 μm) and the aorta, as previously described 4-7. Adventitia of arterial rings was carefully removed and rings were mounted and isometric tension was measured by a force transducer (Nihon Kohden Co). Rings were precontracted with prostaglandin F₂₅. The contributions of vasodilator PGs, NO and EDHF to ACh-induced endothelium-dependent relaxation were determined by the inhibitory effect of indomethacin (10⁻⁵ mol/L), L-NNA (10⁻⁴ mol/L) in the presence of indomethacin, and a combination of 100 nmol/L charybdotoxin [an inhibitor of large- and intermediate-conductance calcium-activated
potassium (KCa) channels] and 1 μmol/L apamin (an inhibitor of small-conductance KCa channels) in the presence of indomethacin and L-NNA, respectively. Endothelium-independent relaxations to SNP and NS1619 (an opener of KCa channels) were examined. To examine the involvement of endothelium-derived H2O2 in the EDHF-mediated responses, the inhibitory effect of catalase, a specific scavenger of H2O2, was examined.

Electrophysiological experiments
The rings of small mesenteric arteries were placed in experimental chambers perfused with 37°C Krebs solution containing indomethacin (10⁻⁵ mol/L) and L-NNA (10⁻⁴ mol/L) bubbled with 95% O₂ and 5% CO₂. A fine glass capillary microelectrode was impaled into the smooth muscle from the adventitial side of mesenteric arteries, and changes in membrane potentials produced by ACh were continuously recorded.

Western blot analysis
Aorta and all of the mesenteric tissues were homogenized and the proteins were extracted. The same amount of extracted protein (10–20 μg) was loaded for SDS-PAGE immunoblot analysis and transferred to polyvinylidene difluoride (PVDF) membranes. The membrane was immunoblotted with anti-eNOS (BD transduction Lab.), anti-nNOS (Zymed Laboratories) and anti-β-actin (Abcam). After incubating with HRP-conjugated anti-mouse or anti-rabbit IgG antibody, blots were visualized by the enhanced chemiluminescence system (ECL Western Blotting Detection kit, GE healthcare). Each band was normalized by corresponding value of β-actin as an internal control. Densitometric analysis was performed by Image J (NIH) Software.

Histological analysis
Mesenteric arteries, aorta and adipose tissue were fixed for 24-30 hours at room temperature in zinc fixative (BD Pharmingen) and embedded in paraffin. The sections were mounted on glass slides and depleted of paraffin with xylene. After blocking of endogenous biotin and avidin binding sites, sections were subjected to immunohistochemical staining overnight at 4°C with an anti-F4/80 monoclonal antibody (Abcam), anti-CD3 (Dako), and anti-Ly6G (R&D Systems). Immune complexes were detected with biotinylated secondary antibodies, horseradish-peroxidase-conjugated streptavidin, and the peroxidase substrate diaminobenzidine. After staining with hematoxylin, mounting solution and cover slips were added to the sections. Slides were observed with a light microscope. Macrophage infiltration in adipose tissue was quantified by calculating the ratio of nuclei of F4/80-positive cells to total nuclei in 20 fields.
Immunofluorescence staining
Aorta and mesenteric arteries were fixed by immersion in solution of zinc fixative. After washing in PBS containing sucrose, the vascular strips were embedded in OCT compound and cut into 6μm thick slices. Anti-CD31 (BD Pharmingen), anti-eNOS (BD transduction Lab.), anti-nNOS (Santa Cruz Biotechnology) and Cy3 conjugated monoclonal anti-α-smooth muscle actin (Sigma-Aldrich) antibodies were applied and incubated overnight at 4°C, followed by incubation with secondary antibodies. Cy3 conjugated anti-α-smooth muscle actin and Alexa Fluor 488 conjugated anti-GFP (Invitrogen) antibodies were applied and incubated 1 hour at room temperature. Slides were viewed with a fluorescence microscopy (BIOREVO, Keyence).

Flow cytometry analysis to assess EPC
EPC numbers in peripheral blood were analysed as described 9-11. Whole blood was lysed and after centrifugation (5 min, 400xg, RT), the supernatant was aspirated and the lysing/centrifugation/aspiration steps were repeated. The cell pellet was resuspended in 1%FBS/PBS. After centrifugation (5min, 400xg, RT), cells were resuspended in 1% FBS/PBS with murine CD16/CD32 Fc Block (BD Pharmingen), incubated for 10 min on ice, followed by 30 min incubation on ice with FITC-conjugated anti-mouse stem cell antigen 1 (Sca-1) and Phycoerythrin (PE)-conjugated anti-mouse fetal-liver kinase 1 (Flk-1) antibodies (BD Pharmingen) or appropriate isotype control. Cells resuspended in 1% FBS/PBS were analysed using a FACS analysis. Based on forward and side scatter, blood mononuclear cells were gated electronically and displayed in a two-color dot plot. Data were analysed using FACSDiva (BD Biosciences), and 50,000 events were counted per sample.

Blood and plasma analysis
Blood cell counts were determined using a multi-automatic blood cell counter for animals (MICROS LC-152, Horiba). The plasma levels of lipids were analyzed with a high-performance liquid chromatography system by Skylight Biotech 12. Plasma adiponectin levels were determined with an ELISA kit (Otsuka Pharmaceutical Co Ltd).

Glucose tolerance tests
For the glucose tolerance test, mice were fasted overnight. Glucose (1 g/kg body weight) was injected intraperitoneally and blood was collected from the tail vein at different time points 13. Blood glucose test was carried out using Glutest-ace R (Sanwa Kagaku Kenkyusho Co).

Drugs and Solution
Recombinant mouse adiponectin (500 μg/kg body weight; R&D systems) or PBS was intraperitoneally injected into male eNOS−/− mice at the age of 13 weeks once daily for 7 days. Organ chamber experiments were performed at 20 h after the last injection.

The ionic composition of the Krebs solution was as follows (mmol/L): Na+ 144, K+ 5.9, Mg2+ 1.2, Ca2+ 2.5, H2PO4− 1.2, HCO3− 24, Cl− 129.7, and glucose 5.5. ACh, NS1619, indomethacin, L-NNA, charybdotoxin and apamin were obtained from Sigma Chemical Co and SNP from Maruishi Seiyaku. Indomethacin was dissolved in 10−2 mol/L Na2CO3 and NS1619 in dimethyl sulfoxide. Other drugs were dissolved in distilled water.

Supplemental Figures

Online Figure I.  Endothelium-dependent and -independent relaxations of mesenteric artery with or without endothelium in WT-BM eNOS−/− mice.

(A) Endothelium-dependent relaxations of mesenteric artery to ACh in the presence of indomethacin and L-NNA were abolished by endothelium removal.  (B) Endothelium-independent relaxations to SNP were comparable between with and without endothelium.  (+)Endothelium, indomethacin and L-NNA; (-)Endothelium, endothelium removal.  Results are expressed as means ± SEM.
Online Figure II. Endothelium-dependent and -independent relaxations of WT mice with or without catalase.

Endothelium-dependent relaxations of mesenteric artery to ACh (A) were inhibited by catalase, whereas catalase had no inhibitory effect in the aorta (B). Endothelium-independent relaxations to SNP (C, D) were comparable regardless of the presence and absence of catalase in both arteries. Indo, indomethacin. Results are expressed as means ± SEM.
Online Figure III. Endothelium-independent relaxations of mesenteric arteries and the aorta.

Endothelium-independent relaxations to NS1619 (a direct opener of \( K_{Ca} \) channel) (A) and sodium nitroprusside (SNP, an NO donor) (B) were comparable between eNOS\(^{-/-}\) mice transplanted with WT-BM and those with eNOS\(^{-/-}\)-BM. This was also the case for the aorta (C, D). (A) Catalase had no effects on the responses. Results are expressed as means ± SEM.
Online Figure IV.  Immunofluorescence staining of mesenteric arteries and the aorta in GFP<sup>+</sup>BM eNOS<sup>−/−</sup> mice and immunohistochemical stainings for F4/80, CD3 and Ly6G.

(A) GFP-positive BM derived cells (blue arrows) were noted in the adventitia of mesenteric artery, but not in endothelium, intima or media of mesenteric artery (left) and the aorta (right).  Red indicates α-smooth muscle actin, green GFP, blue DAPI.  (B) Immunohistochemical stainings with F4/80, CD3 and Ly6G were performed.  F4/80-positive cell (blue arrows) was noted in the adventitia.  Bar, 25 μm.
Online Figure V. Immunofluorescence staining of mesenteric arteries.

(A) eNOS was not stained at all and CD31 was stained only in the endothelium in WT-BM eNOS−/− mice. (B) nNOS was stained in all layer of mesenteric artery and co-localized with CD31. (C) WT mice were stained with CD31 (eNOS as a positive control). (D) eNOS−/−/nNOS−/− mice were stained with CD31 (nNOS as a negative control). Bar, 25 μm.
Online Figure VI. FACS analysis for circulating Sca-1+/Flk-1+ EPC in WT, WT-BM eNOS−/− and eNOS−/−-BM eNOS−/− mice.

(A) Representative dot plots of forward scatter (FSC) and side scatter (SSC) of circulating blood cells and a gate of mononuclear cells.  
(B) Representative 2-color (Sca-1 and Flk-1) flow cytometry dot plots of mononuclear cells.  
(C) There was no difference in the number of Sca-1+/Flk-1+ EPC among the 3 groups.  Results are expressed as means ± SEM.
Online Figure VII. Endothelium-independent relaxations of mesenteric arteries from eNOS<sup>-/-</sup>/adiponectin<sup>-/-</sup> mice.

Endothelium-independent relaxation responses to NS1619 (A) and those to SNP (B) were comparable between control eNOS<sup>-/-</sup>/adiponectin<sup>-/-</sup> mice and those transplanted with WT-BM. Results are expressed as means ± SEM.
Online Figure VIII. Endothelium-independent relaxations of mesenteric arteries from eNOS$^+/−$/nNOS$^+/−$ mice. Endothelium-independent relaxations to NS1619 (A) and SNP (B) were comparable between control eNOS$^+/−$/nNOS$^+/−$ mice and those transplanted with WT-BM. Results are expressed as means ± SEM.
Online Figure IX. Endothelium-independent relaxations of mesenteric arteries from adiponectin- or PBS-treated eNOS−/− mice.

Endothelium-independent relaxations to NS1619 (A) and SNP (B) were comparable between adiponectin-treated and PBS-treated groups. Results are expressed as means ± SEM.
