Age-Associated Sirtuin 1 Reduction in Vascular Smooth Muscle Links Vascular Senescence and Inflammation to Abdominal Aortic Aneurysm

Hou-Zao Chen,* Fang Wang,* Peng Gao,* Jian-Fei Pei,* Yue Liu, Ting-Ting Xu, Xiaoqiang Tang, Wen-Yan Fu, Jie Lu, Yun-Fei Yan, Xiao-Man Wang, Lei Han, Zhu-Qin Zhang, Ran Zhang, Ming-Hui Zou, De-Pei Liu

Rationale: Uncontrolled growth of abdominal aortic aneurysms (AAAs) is a life-threatening vascular disease without an effective pharmaceutical treatment. AAA incidence dramatically increases with advancing age in men. However, the molecular mechanisms by which aging predisposes individuals to AAAs remain unknown.

Objective: In this study, we investigated the role of SIRT1 (Sirtuin 1), a class III histone deacetylase, in AAA formation and the underlying mechanisms linking vascular senescence and inflammation.

Methods and Results: The expression and activity of SIRT1 were significantly decreased in human AAA samples. SIRT1 in vascular smooth muscle cells was remarkably downregulated in the suprarenal aortas of aged mice, in which AAAs induced by angiotensin II infusion were significantly elevated. Moreover, vascular smooth muscle cell–specific knockout of SIRT1 accelerated angiotensin II–induced formation and rupture of AAAs and AAA-related pathological changes, whereas vascular smooth muscle cell–specific overexpression of SIRT1 suppressed angiotensin II–induced AAA formation and progression in Apoe<sup>−/−</sup> mice. Furthermore, the inhibitory effect of SIRT1 on AAA formation was also proved in a calcium chloride (CaCl<sub>2</sub>)–induced AAA model. Mechanistically, the reduction of SIRT1 was shown to increase vascular cell senescence and upregulate p21 expression, as well as enhance vascular inflammation. Notably, inhibition of p21-dependent vascular cell senescence by SIRT1 blocked angiotensin II–induced nuclear factor-κB binding on the promoter of monocyte chemoattractant protein-1 and inhibited its expression.

Conclusions: These findings provide evidence that SIRT1 reduction links vascular senescence and inflammation to AAAs and that SIRT1 in vascular smooth muscle cells provides a therapeutic target for the prevention of AAA formation. (Circ Res. 2016;119:1076-1088. DOI: 10.1161/CIRCRESAHA.116.308895.)

Key Words: aging ■ angiotensin II ■ inflammation ■ aortic aneurysm, abdominal ■ SIRT1 protein, human

Abdominal aortic aneurysms (AAAs), characterized by a permanent, localized dilatation (ballooning) of the abdominal aorta that exceeds the normal diameter by >50%, are the most common form of aortic aneurysm. AAA rupture and the associated catastrophic physiological insult carry an overall mortality rate in excess of 80%; ruptured AAAs are the 13th leading cause of death in the United States. Pathologically, AAAs are characterized by increased inflammatory cell infiltration, aberrant oxidant stress, medial elastin degradation, and medial collagen deposition. Apart from surgery, few medical treatments have been shown to prevent AAA development and growth, primarily as a result of the limited understanding of its pathogenic mechanisms. AAAs are found in up to 8% of men aged >65 years. AAA incidence increases steeply by 40% every 5 years in men who...
are >65 years old, indicating that age is a major risk factor for AAAs.² Although age-related alterations such as enhanced inflammatory responses, vascular stiffening, and oxidative stress make aged arteries more susceptible to vascular diseases, such as atherosclerosis,⁵⁻⁷ the reasons why AAAs are often observed in patients with advanced age (>65 years) and how advanced age dramatically accelerates the development and progression of aneurysms in abdominal aortas remain unknown. Furthermore, little is known about the contributions of vascular aging in AAAs and whether an alteration of age-related molecules is required for AAA initiation and progression.

Sir2 (silent information regulator 2) proteins (sirtuins), a conserved nicotinamide adenine dinucleotide–dependent protein deacetylase, play critical roles in improving metabolism and healthspan.⁸⁻¹⁰ Sir2 (Sir1, Sirtuin 1), the best characterized mammalian sirtuin, is highly expressed in the vasculature¹¹ and is an important modulator of cardiovascular functions in health and disease. Several studies from our laboratory and others indicate that SIRT1 protects against stress-induced vascular remodeling,¹²⁻¹⁵ aortic stiffness and dissection,¹⁴⁻¹⁵ and atherosclerosis in mice,¹⁶⁻¹⁸ suggesting a critical role of SIRT1 in vascular diseases. The activation of SIRT1 confers protective effects on atherosclerosis involving vascular endothelial and smooth muscle cell senescence.¹⁸⁻²⁰ Despite that advanced age is a known risk factor for AAAs, whether advanced age accelerates AAA formation in mice and the molecular mechanisms that link vascular cell senescence and AAA formation remain elusive. Here, we report that the expression and activity of SIRT1 were significantly decreased in human AAA samples. Age-associated SIRT1 reduction in vascular smooth muscle cells (VSMCs) of abdominal aortas increases their susceptibility to AAAs in mice. The reduction of SIRT1 was shown to increase vascular cell senescence, upregulate the expression of p21, and enhance inflammatory cell recruitment for vascular inflammation, which predisposes aortas to AAAs.

**Methods**

An expanded Materials and Methods section is available in the Online Data Supplement.

**Human Aortic Samples**

All protocols using human aortic samples were approved by the Ethical Committee of Chinese Academy of Medical Sciences and Peking Union Medical College. We obtained human AAA samples from 6 patients undergoing open surgical repair. AAA was diagnosed by ultrasound scanning before the operation. The control samples were trimmed from the adjacent nonaneurysmal aortic segments from the same patients. Information on the enrolled patients is provided in Online Table I.

**Animal Experiments**

All animal protocols were approved by the Animal Care and Use Committee at the Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences, and Peking Union Medical College. We used 2- to 3-month-old C57BL/6J male mice as young mice and 18- to 20-month-old C57BL/6J male mice as old mice. SIRT1-VSMC–specific transgenic (SV-Tg) Apoe⁺/− mice were generated by crossing SV-Tg mice⁺/− with Apoe⁻/− mice. We utilized a Cre/LoxP strategy to yield SIRT1-VSMC–specific knockout (SV-KO) mice. Age-matched male mice (young and old) and 4- to 6-month-old male mice (Apoe⁻/−, SV-Tg Apoe⁺/−; SV-KO, wild-type [WT]; Apoe⁻/−, p2 F⁻/−Apoe⁺/−) were infused with angiotensin II (Ang II) at a dosage of 1.44 mg/kg per day or saline for 4 weeks as previously described.²¹ In the CaCl₂-induced AAA model, we induced AAA in both SV-KO (3 weeks) and SV-Tg (6 weeks) mice by periaortic application of 0.5 mol/L CaCl₂ as described previously.²²

**SIRT1 Deacetylase Activity Assay**

SIRT1 activity was assayed using a SIRT1 deacetylase activity assay kit (Sigma) according to the manufacturer’s instructions using microplate reader (Synergy 4; BioTek).

**Senescence-Associated β-Galactosidase Activity Assay**

Senescence-associated β-galactosidase (SA-β-gal) activity was quantitatively measured according to the rate of conversion of 4-methylumbelliferone into the fluorescent hydrolysis product 4-methylumbelliflorone at pH 6.0, as described previously.²³ The whole-aorta tissues were stained to determine SA-β-gal activity using a commercial kit (ab65531; Abcam) according to the manufacturer’s instructions, as previously reported.²³

**Statistical Analyses**

For all statistical tests, a P<0.05 was considered statistically significant, and all tests were 2 tailed. Normality tests were assessed via the Shapiro–Wilk statistics with SPSS software package (version 19.0). All statistical analyses were performed using GraphPad Prism (version 6.0.1) software.

**Results**

**Reduction of SIRT1 Expression and Activity in Human AAA Formation**

To establish the impact of AAAs on SIRT1, we first examined the expression of SIRT1 in human AAA samples. Human AAA tissues and their control adjacent aortic sections without aneurysm were obtained from patients undergoing open surgery (Online Table I). As expected, proaneurysmal molecules, such as matrix metalloproteinase 2 (MMP2), human membrane type 1 MMP, and monocyte chemoattractant protein-1 (MCP-1/CCL2), were significantly elevated in human AAA sections (Figure 1A and 1B; Online Figure 1A) compared with adjacent nonaneurysmal aortic sections. The activity of SIRT1 in human AAA samples was also significantly lower than that in adjacent nonaneurysmal aortic sections (Figure 1C). These results suggest that SIRT1 reduction is involved in the development of human AAA formation.
Reduced SIRT1 Expression and Activity in the Aged Mouse Aortas

Because advanced age is a known risk factor for AAAs, we examined the effects of age on SIRT1 expression and activity in mouse aortas. SIRT1 activity was significantly lower in the whole aortas of aged mice than that of their young counterparts (Figure 1D). SIRT1 expression was decreased in whole aortas and substantially reduced in the abdominal aortas of aged mice compared with aortas from young mice (Figure 1E; Online Figure IB and IC). Moreover, the decrease in SIRT1 expression was mainly observed in the medial VSMCs of the suprarenal aortas (Figure 1F and 1G), where AAAs most often develop in mice with Ang II infusion. Therefore, the reduction of SIRT1 activity and expression in aged aortas may be linked to their susceptibility to AAAs.

Figure 1. SIRT1 (Sirtuin 1) is decreased in human abdominal aortic aneurysm (AAA) samples and aged mouse abdominal aortas.

A, Representative Western blots of SIRT1, membrane type 1-matrix metalloproteinase (MT1-MMP), monocyte chemoattractant protein-1 (MCP-1/CCL2), and MMP2 in human AAA samples and adjacent control aortas. B, Densitometric analysis of the protein levels of SIRT1, MT1-MMP, MCP-1/CCL2, and MMP2 in human AAA samples and adjacent control aortas (n=6). C, Quantitative analysis of SIRT1 activity in homogenates of human AAA samples and adjacent nonaneurysmal aortic sections (n=6). D, Fluorescence intensity indicating SIRT1 activity in homogenates of young mouse compared with that of the aged mouse (n=6). E, Representative Western blots of SIRT1 and p21 in abdominal aortas (AA) from aged and young mice. Adventitial tissue was removed from the aorta as much as possible, and each sample was pooled from 3 abdominal aortas together for immunoblot analysis. F, Representative immunofluorescent staining of SIRT1, α-smooth muscle actin (SMA), and 4’,6-diamidino-2-phenylindole (DAPI) in suprarenal aortas of young and aged mice (scale bars, 50 µm). G, Densitometric analysis of the protein level of SIRT1, which is normalized to α-SMA, in suprarenal aortas of young and aged mice (n=9). Three different visual fields were captured in each slide.

Aging Increases Ang II–Induced AAA Formation in Mice

Acute infusion of Ang II recapitulates many aspects of AAAs and is widely used to study AAAs. To clarify the effects of advanced age on AAA formation, 22 C57BL/6J male mice aged 18 to 20 months (aged) and 23 C57BL/6J male mice aged 2 to 3 months (young) were infused with the same dose of Ang II for 4 weeks. In saline-infused groups, 1 in 16 aged mice displayed expanded abdominal aorta to the extent of AAA, whereas none of the young mice displayed AAA formation (Figure 2A and 2B). In Ang II–infused groups, the AAA
incidence in aged mice was 86.4% (19/22), much higher than
the 13.0% (3/23) observed in young mice (Figure 2A and 2B).
Approximately 22.7% (5/22) of Ang II–infused aged mice
died from aortic rupture, whereas only 4.3% (1/23) of Ang II–
infused young and aged mice. F and G, mRNA levels of monocyte chemoattractant protein-1 (MCP-1/CCL2; F) and matrix metalloproteinase 2 (MMP-2; G) detected by real-time polymerase chain reaction in aorta homogenates from young and aged mice infused with saline or Ang II for 4 wk. H, Representative immunostaining with CD45 in the suprarenal aortic wall of young and aged mice infused with saline or Ang II for 4 wk. The arrows show representative staining with CD45 antibody. I, The number of CD45-positive cells accumulating in the suprarenal aortic wall of saline- and Ang II–infused mice (n=8–23). SV-KO indicates SIRT1 (Sirtuin 1)–vascular smooth muscle cell (VSMC)–specific knockout; and WT, wild-type.

VSMC-Specific Ablation of SIRT1 Exacerbates Ang II–Induced AAA Formation and Related Pathological Changes In Vivo
To establish a causative link between the reduction of SIRT1 and AAA formation, we crossbred a conditional allele of Sirt1 (Sirt1flx) mice with mice with Cre recombinase driven by the
SM22α promoter to obtain SV-KO (SM22-Cre<sup>+/−</sup>; Sirt1<sup>fl/fl</sup>) mice (Online Figure IIA–IID), and their Sirt1<sup>fl/fl</sup> littermates were used as WT controls. Although SIRT1 activity and expression in the aortas of SV-KO mice were markedly reduced compared with their littermates (Online Figure IIE and IIF), there was no difference in the gross morphology of aortas between saline-infused SV-KO and WT mice (Figure 3A). However, 4 weeks of Ang II infusion caused a 64.2% (34/53) incidence of AAA in SV-KO mice compared with 19.6% (9/46) in WT mice (Figure 3B). Approximately 34.0% (18/53) of Ang II–infused SV-KO mice died because of aortic rupture, whereas only 8.7% (4/46) of Ang II–infused WT mice died (Figure 3C; Online Table II). To exclude the effect of SM22 deficiency after Cre knockin, we treated 10 SM22-Cre<sup>+/−</sup>; Sirt1<sup>+/+</sup> mice with Ang II for 4 weeks and found that only 2 developed AAAs, suggesting that SM22 deficiency in 1 allele does not influence Ang II–induced AAA formation. In addition, compared with Ang II–treated WT mice, the maximal abdominal aortic diameter, the ratio of total aortic weight to body weight, and the elastin degradation score were remarkably higher, whereas the elastic fiber content was significantly lower in Ang II–treated SV-KO mice (Figure 3D–3F; Online Figure IIIA and IIIB). The systolic blood pressure, heart rate, and serum lipid levels after Ang II infusion did not differ between SV-KO mice and WT mice (Online Tables III and IV).

Aberrant levels of oxidative stress play critical roles in AAA initiation and progression. Therefore, we analyzed medial oxidative stress by immunostaining for 3-nitrotyrosine and 8-hydroxydeoxyguanosine (8-OH-dG), 2 oxidative stress

Figure 3. Vascular smooth muscle cell (VSMC)–specific SIRT1 (Sirtuin 1) ablation promotes abdominal aortic aneurysm (AAA) formation and vascular pathophysiological mechanisms induced by angiotensin II (Ang II) infusion. All mice were infused with saline or Ang II for 4 wk. A, Representative photographs showing macroscopic features of aneurysms induced by Ang II. The arrow shows a typical AAA (scale bars, 5 mm). B and C, The incidence (B) and survival curve (C) of Ang II–induced AAA in SIRT1-VSMC–specific knockout (SV-KO) mice (n=53) compared with that in wild-type (WT) mice (n=46). There was no AAA formation in saline-infused mice (n=12), and the number of mice that developed AAA included the deaths caused by abdominal aortic rupture. D, The maximal abdominal aortic diameter in saline- and Ang II–infused mice. E, Representative staining with elastin and elastin degradation score in suprarenal aortas from saline- and Ang II–infused mice. The magnified photographs were taken at the location where the most severe elastin degradation occurred (scale bars, 150 and 50 µm; magnified photographs). F, Aorta homogenates were obtained from WT and SV-KO mice infused with saline or Ang II for 4 wk. Western blot and densitometric analysis of the protein levels of monocyte chemoattractant protein-1 (MCP-1/CCL2) and matrix metalloproteinase 2 (MMP2) in aorta homogenates (n=4–6).
SIRT1 Reduction Promotes AAAs

Biomarkers. Aortas from Ang II–infused SV-KO mice exhibited a significant increase in the levels of both 3-nitrotyrosine and 8-OH-dG compared with those of Ang II–infused WT mice (Online Figure IIIC and IIID). In saline-infused mice, few inflammatory cells were found in the suprarenal aortic wall (Online Figure IVA). After Ang II infusion, inflammatory cell infiltration was increased in the aortas of Ang II–infused SV-KO mice compared with those of Ang II–infused WT mice (Online Figure IIIC and IIID). In saline-infused mice, few inflammatory cells were found in the suprarenal aortic wall (Online Figure IVA). After Ang II infusion, inflammatory cell infiltration was increased in the aortas of Ang II–infused SV-KO mice compared with those of Ang II–infused WT mice (Online Figure IIIC and IIID).

VSMC-Specific Overexpression of SIRT1 Suppresses Ang II–Induced AAA Formation and Related Pathological Changes in ApoE−/− Mice

ApoE−/− mice with Ang II infusion is a widely used animal model for AAA formation,25,26 and the incidence of AAAs in ApoE−/− mice in response to Ang II is much greater than that in age-matched WT mice.21,25,26,29 Therefore, we studied whether SIRT1 VSMC-specific overexpression could reduce AAA development in vivo by examining the above-mentioned index in aortas obtained from VSMC-specific SIRT1 transgenic mice (Online Figure IVD). These results indicate that the VSMC-specific ablation of SIRT1 exacerbates AAA formation and related pathological changes.

Figure 4. Vascular smooth muscle cell (VSMC)-specific SIRT1 (Sirtuin 1) overexpression prevents abdominal aortic aneurysm (AAA) formation and vascular pathophysiological mechanisms induced by angiotensin II (Ang II) infusion. All mice were infused with saline or Ang II for 4 wk. A, Representative photographs showing macroscopic features of aneurysms induced by Ang II. The arrow shows a typical AAA (scale bars, 5 mm). B and C, The incidence (B) and survival curve (C) of Ang II–induced AAA in SIRT1-VSMC–specific transgenic (SV-Tg) ApoE−/− mice (n=29) compared with those in ApoE−/− mice (n=33). There was no AAA formation in saline-infused mice (n=10), and the number of mice that developed AAA included the deaths caused by abdominal aortic rupture. D, The maximal abdominal aortic diameter in saline- and Ang II–infused mice. E, Representative staining with elastin and elastin degradation score in suprarenal aortas from saline- and Ang II–infused mice. The magnified photographs were taken at the location where the most severe elastin degradation occurred (scale bars, 150 and 50 μm; magnified photographs). F, Aorta homogenates were obtained from ApoE−/− and SV-Tg ApoE−/− mice infused with saline or Ang II for 4 wk. Western blot and densitometric analysis of the protein levels of monocyte chemoattractant protein-1 (MCP-1/CCL2) and matrix metalloproteinase 2 (MMP2) in aorta homogenates (n=4–6).
mice (SV-Tg mice) in the Apoe<sup>−/−</sup> background (SV-Tg Apoe<sup>−/−</sup> mice) with or without Ang II infusion for 4 weeks. In saline-infused groups, no AAAs were found among Apoe<sup>−/−</sup> and SV-Tg Apoe<sup>−/−</sup> mice. Ang II infusion for 4 weeks caused AAAs in 81.8% (27/33) of Apoe<sup>−/−</sup> mice (Figure 4A and 4B), which was similar to the incidence of Ang II–induced AAAs in aged mice. Only 27.6% (8/29) of SV-Tg Apoe<sup>−/−</sup> mice developed AAAs after Ang II infusion. Approximately 33.3% (11/33) of Apoe<sup>−/−</sup> mice died because of aortic rupture during Ang II treatment, but the death rate of Ang II–infused SV-Tg Apoe<sup>−/−</sup> mice was only 10.3% (3/29) (Figure 4A through 4C; Online Table II). Compared with Ang II–treated Apoe<sup>−/−</sup> mice, the maximal abdominal aortic diameter, the ratio of total aortic weight to body weight, and the elastin degradation score were remarkably lower, whereas the elastic fiber content was significantly higher in Ang II–treated SV-Tg Apoe<sup>−/−</sup> mice (Figure 4D and 4E; Online Figure VA and VB) without noticeable effects on hemodynamic and lipid metabolic indices (Online Tables III and IV). Moreover, the VSMC-specific SIRT1 transgene remarkably attenuated the increased levels of oxidative stress (Online Figure VC and VD), vascular inflammation, MCP-1/CCL2 expression (Figure 4F; Online Figure VIA and VIB) and MMP2 activation (Figure 4F; Online Figure VIC and VID) caused by Ang II infusion in Apoe<sup>−/−</sup> mice. These results indicate that SIRT1 overexpression in VSMCs ameliorates the increased AAA formation and related pathological changes.

**SIRT1 in VSMCs Inhibits Calcium Chloride–Induced AAA Formation**

To further investigate whether the inhibitory effects of SIRT1 in VSMCs on AAA formation are independent of Ang II, another type of mouse AAA model, calcium chloride (CaCl<sub>2</sub>)–induced AAAs was applied in both SV-KO and SV-Tg mice. We found that 3 weeks after CaCl<sub>2</sub> treatment, the ratio of total aortic weight to body weight and the maximal external and internal abdominal aortic diameter were significantly increased in SV-KO mice compared with those of their littermates (Figure 5A through 5D), and a substantial increase in the elastin degradation score was also observed (Figure 5E and 5F). Moreover, in situ immunochemical staining showed that compared with WT mice, SV-KO mice displayed significantly increased MCP-1/CCL2 and MMP-2 protein expression after CaCl<sub>2</sub> treatment (Online Figure VIA through VIID). To determine the protective role of SIRT1 transgene...
in AAAs, we treated SV-Tg and their WT controls with CaCl₂ for 6 weeks. In contrast, we found that the ratio of total aortic weight to body weight and the maximal external and internal abdominal aortic diameter were significantly decreased in SV-Tg mice compared with those of their littermates after CaCl₂ treatment (Online Figure VIIA through VIIIF). SIRT1 overexpression in VSMCs was also found to significantly inhibit CaCl₂-induced MCP-1/CCL2 and MMP-2 protein expression (Online Figure VIIIG and VIIIH). These results indicate that SIRT1 in VSMCs plays a protective role in CaCl₂-induced AAA formation.

Figure 6. Vascular smooth muscle cell (VSMC)–derived SIRT1 (Sirtuin 1) is crucial for suppression of vascular cell senescence in angiotensin II (Ang II)–induced abdominal aortic aneurysms (AAAs). All mice were infused with saline or Ang II for 4 wk. A, C, and E, Representative photographs and densitometric analysis of senescence-associated β-galactosidase (SA-β-gal)–stained aortas from wild-type (WT) and SIRT1-VSMC–specific knockout (SV-KO; A), Apoe⁻/- and SIRT1-VSMC–specific transgenic (SV-Tg) Apoe⁻/- (C), young and aged (E) mice infused with saline or Ang II (scale bars, 5 mm; n=6 per group). B, D, and F, Representative images of SA-β-gal–stained transverse sections of suprarenal abdominal aortas from WT and SV-KO (B), Apoe⁻/- and SV-Tg Apoe⁻/- (D), and young and aged (F) mice infused with saline or Ang II. The blue region was positively stained, and nuclei were counterstained using Nuclear Fast Red (scale bars, 50 µm).

SIRT1 Is Crucial for Suppression of Vascular Cell Senescence and p21 Expression in AAAs

Ang II infusion accelerates vascular cell senescence in vivo, which can be characterized by SA-β-gal staining, as reported in the previous study, 30 and we found that SA-β-gal–positive staining was mainly located in the media of the aortas (Online Figure IXA), suggesting a role of medial VSMC senescence in Ang II–induced AAAs. To investigate the role of SIRT1 in vascular cell senescence, SA-β-gal staining was performed in the aortas of Ang II– or saline-infused SV-KO mice and SV-Tg Apoe⁻/- mice and their respective controls. In saline-infused groups, few obvious SA-β-gal–positive areas were detected in both SV-KO mice and SV-Tg Apoe⁻/- mice. Ang II infusion led to the enlargement of SA-β-gal–positive regions in the aortas of WT mice, whereas the SIRT1-specific loss of function in VSMCs further increased the areas of SA-β-gal–positive staining (Figure 6A). The increase of SA-β-gal–positive staining in the aortas of SV-KO mice mainly occurred at medial VSMCs (Figure 6B). Moreover, Ang II–induced vascular cell senescence was further supported by the results of assays for SA-β-gal activity in the homogenates of whole aortas (Online Figure IXB). In contrast, SA-β-gal staining was suppressed in SV-Tg Apoe⁻/- mice (Figure 6C). Notably, SA-β-gal–positive staining in medial VSMCs was
markedly inhibited in SV-Tg Apoe<sup>−/−</sup> mice (Figure 6D). As expected, the SA-β-gal activity assay also confirmed the anti-aging effect of SIRT1 overexpression (Online Figure IXC). Furthermore, vascular aging was demonstrated by increased pulse wave velocity in the left common carotid artery in vivo.31,32 As expected, Ang II caused a modest increase in pulse wave velocity in WT mice, whereas it robustly increased the value in SV-KO mice (Online Figure IXD), and this trend was reversed in SV-Tg Apoe<sup>−/−</sup> mice (Online Figure IXE). These results indicate that the manipulation of SIRT1 expression or activity affects Ang II–induced vascular cell senescence in AAAs.

To further investigate the role of vascular cell senescence in aging-increased AAA formation, we examined SA-β-gal–positive areas in the aortas of young and aged mice with or without Ang II infusion. As shown in Figure 6E, the levels of SA-β-gal–positive areas in the aortas of saline-infused young and aged mice were low, and there was no difference between aged and young aortas; similar results were observed for SA-β-gal activity (Online Figure IXF), suggesting that vascular cell senescence was low and unaltered in aortas with advanced age. However, Ang II infusion significantly increased SA-β-gal–positive areas and SA-β-gal activity in the aortas of aged mice compared with those of young mice (Figure 6E; Online Figure IXF). The increase of SA-β-gal staining and SA-β-gal activity caused by Ang II was significantly greater in aged mice than that in young mice (Figure 7C). Similarly, increased p21 expression was found in human AAA samples (Figure 7D). These results provide evidence that the increased vascular senescence and deregulated p21 expression caused by the reduction of SIRT1 participates in the promotional effect of aging on AAAs.

**Suppression of p21 in VSMCs Abolishes Enhanced Nuclear Factor-κB Activation and MCP-1/CCL2 Expression by SIRT1 Inhibition**

To further explore how SIRT1 reduction in VSMCs promotes Ang II–induced AAAs, gene expression microarray analysis was performed using RNA isolated from the aortas of Ang II–treated SV-KO mice and their Sirt1<sub>flox/flox</sub> littermates. Interestingly, analysis using ingenuity pathway analysis software revealed that the inflammatory response pathway was the pathway most affected by SIRT1 deficiency (Online Figure XA and XB and Online Table V), which was consistent with the aforementioned result of Online Figure IVA. Accordingly, nuclear factor (NF)-κB signaling was significantly activated.
and the mRNA levels of a series of NF-κB target genes, including MCP-1/CCL2, were significantly increased in the aortas of SV-KO mice compared with the WT mice after 4 weeks of Ang II infusion (Online Figure XIA through XID) in parallel with their protein levels as shown in Figures 3F and Online Figure IVB. Moreover, regulator effects in ingenuity pathway analysis further showed that CCR2, the receptor for MCP-1/CCL2, has the highest Consistency Score of all the regulators for cell recruitment, infiltration, and activation (Online Figure XII and Online Table VI). Furthermore, chromatin immunoprecipitation (ChIP) assays confirmed that VSMC-specific ablation of SIRT1 increased the binding activity of NF-κB on MCP-1/CCL2 promoter after Ang II infusion (Online Figure XIII), whereas a significantly lower binding level of NF-κB on MCP-1/CCL2 promoter was observed in the aortas of Ang II–infused SV-Tg Apoe−/− mice compared with their Apoe−/− littermates (Online Figure XIV), suggesting that SIRT1 reduction facilitates NF-κB–mediated transcriptional activation of MCP-1/CCL2 in AAAs. The results indicated that p21 knockout not only protects Apoe−/− mice against Ang II–induced AAA formation (Online Figure XVA through XVC) as previously reported but also almost completely blocked the expression of MCP-1/CCL2 and MMP-2 in Ang II–induced AAAs (Online Figure XVD and XVE).

Thus, we suspected that the promotional effect of SIRT1 reduction on Ang II–induced MCP-1/CCL2 expression might rely on the existence of p21 and VSMC cell senescence. To verify this hypothesis, adenovirus-mediated p21 RNA interference (RNAi) was introduced in VSMCs isolated from the aortas of SV-KO mice or control WT mice before treated with saline or Ang II. As expected, p21 mRNA level in both saline- and Ang II–treated VSMCs was significantly repressed by transfection of Ad-p21 RNAi (vectors for adenovirus-mediated knockdown of p21; Online Figure XVI). The results of SA-β-gal staining indicated that p21 knockdown not only blocked Ang II–induced VSMC senescence but also eradicated the promotional effect of SIRT1 knockout (Figure 8A and 8B; Online Table VII). Accordingly, Ang II–increased expression of MCP-1/CCL2 in SV-KO
VSMCs was also significantly reduced by p21 knockdown (Figure 8C). Finally, we also performed ChIP assay to detect the binding level of NF-κB on MCP-1/CCL2 promoter in saline- or Ang II–treated human VSMCs infected by either Ad-SIRT1 RNAi or Ad-p21 RNAi or both of them. Three binding sites of NF-κB on human MCP-1/CCL2 promoter by ChIP assays were selected out from the 5 potential binding sites to assess the impact of p21 knockdown to the effect of SIRT1 RNAi on transcriptional activation of MCP-1/CCL2 (Online Figure XVII). The results indicated that p21 knockdown by RNAi almost completely blocked the promotional effect of SIRT1 knockdown on Ang II–increased RelA/p65 binding on the 3 potential NF-κB binding sites of MCP-1/CCL2 promoter (Figure 8D through 8F). These results support that p21-mediated VSMC cell senescence by SIRT1 reduction facilitates the transcriptional activation of MCP-1/CCL2, which may promote inflammatory cell recruitment and vascular inflammation in AAAs.

Discussion

In the present study, we demonstrated that SIRT1 acts as a novel molecular link that retards vascular senescence and inflammation to prevent AAA initiation and development. There are several major findings in this study. First, the expression and activity of SIRT1 were significantly decreased in human AAA samples. Second, SIRT1 in VSMCs was substantially downregulated in the suprarenal aortas of aged mice, in which AAAs induced by Ang II infusion were significantly elevated. Third, SIRT1 reduction in VSMCs amplified Ang II–induced vascular aging and AAA formation in mice in vivo, whereas genetic activation of SIRT1 in VSMCs displayed the opposite effect. The inhibitory effect of SIRT1 on AAA formation was also confirmed in the CaCl₂–induced AAA model. Fourth, the reduction of SIRT1 was shown to increase vascular cell senescence and upregulate p21 expression and enhance vascular inflammation. Moreover, suppression of p21-dependent vascular cell senescence by SIRT1 inhibited Ang II–induced inflammation.

AAA incidence increases steeply by 40% every 5 years in men aged >65 years, indicating that age is a major risk factor for AAAs. Why advanced age (>65 years) precipitates AAA development and progression is unknown. In the present study, we found that SIRT1 protein and activity were significantly suppressed in the aortic VSMCs of aged mice, and vascular cell senescence in the aortas of aged mice was low and comparable to that of young mice under natural conditions. Concomitantly, only a few incidences of spontaneous AAAs were observed in the same conditions. In contrast, AAA formation and vascular cell senescence in SV-KO mice and aged mice were significantly increased by Ang II infusion, indicating that the SIRT1 reduction in advanced age creates an environment that facilitates AAA initiation and progression caused by Ang II, but does not directly instigate AAAs. This conclusion is supported by human epidemiological evidence indicating that aging is a risk factor for AAA and only a small number of men with advanced age develop AAAs. Accumulating evidence has shown that SIRT1 plays an important role in healthy aging and age-related diseases, which suggests that the SIRT1 reduction in advanced age may also predispose individuals to the aging of other tissues and to age-related cardiovascular diseases.

Systemic inflammation has been linked to multiple chronic diseases of aging and may even contribute to their causation. Although increases in chronic inflammation have been detected in the vasculature with age, the molecular mechanisms that link vascular aging and inflammation to AAA formation remain elusive. Previous studies have identified important roles for p53 in promoting aging and NF-κB in mediating inflammatory response, both of which can be targeted by SIRT1. In the present study, we found that SIRT1 reduction increased Ang II–induced VSMC senescence and upregulated p53 acetylation and p21 protein. Inflammatory NF-κB activation and MCP-1/CCL2 were significantly increased in parallel with increased vascular cell senescence. Accordingly, AAA formation was significantly enhanced by SIRT1 reduction in both SV-KO mice and in aged mice (Online Figure XVIII). Moreover, Ang II–activated NF-κB transcription of MCP-1/CCL2 expression was significantly decreased by suppression of p21 in SIRT1 knockout VSMCs. These results suggest that the deregulated SIRT1–p53–p21 axis in VSMCs in response to Ang II accelerates NF-κB–induced vascular inflammation and renders aortas susceptible to AAAs. To the best of our knowledge, this is the first time that a direct link between vascular cell senescence and vascular inflammation to AAA formation by SIRT1 reduction has been reported. Importantly, AAA formation and the related pathological and molecular changes could be effectively inhibited by VSMC-specific overexpression of SIRT1, which provides a potential therapeutic target for AAAs (Online Figure XVIII). However, whether SIRT1 reduction in VSMCs induces NF-κB–mediated vascular inflammation and accelerates AAA formation by downregulation of p53/p21 in vivo requires further investigation. In addition, our results highlight the importance of VSMC senescence in the development of vascular inflammation and AAAs, which is also consistent with the well-known roles of VSMCs in AAA formation.

In summary, our findings indicate that the age-related reduction of SIRT1 in VSMCs predisposes aortas to AAAs by facilitating p21-dependent vascular cell senescence, secretion of inflammatory cell recruitment molecules, and vascular inflammation. These findings indicate a direct link between vascular cell senescence and AAAs through vascular inflammation that provides a deeper understanding of the relationship between aging and age-related vascular diseases.

Acknowledgments

We wish to acknowledge the excellent technical help of De-Long Hao and Xiang Zhao in producing SIRT1-VSMC–specific transgenic and SIRT1-VSMC–specific knockout mice.

Sources of Funding

This work was supported by grants from the National Natural Science Foundation of China (nos. 81422002, 91339201, 31571193, and 31273227) and the National Science and Technology Support Project (2013YQ0309230502 and 2014BAI02B01). Dr Zou’s laboratory was supported by the grants from the National Heart, Lung, and Blood Institute (HL080499, HL105157) and National Institute on Aging (AG047776).
Disclosures

None.

What Is Known?

- In humans, the incidence of abdominal aortic aneurysm (AAA) increases dramatically with age.
- SIRT1 is highly expressed in the vasculature and plays a protective role in vascular remodeling, aortic stiffness and dissection, and atherosclerosis in mice.

What New Information Does This Article Contribute?

- The expression and activity of SIRT1 are significantly decreased in human AAA samples.
- SIRT1 in VSMCs is downregulated in the suprarenal aortas of aged mice, in which AAAs induced by Ang II infusion were significantly elevated.
- VSMC-specific knockout of SIRT1 accelerates Ang II- or CaCl_2-induced AAA formation, whereas VSMC-specific overexpression of SIRT1 displays the opposite effect.

Novelty and Significance

- SIRT1 reduction increases Ang II-induced vascular cell senescence, upregulates the expression of p21 and enhances inflammatory cell recruitment for vascular inflammation in AAAs.

Age is a major risk factor for AAAs. Uncontrolled growth of AAAs is a life-threatening vascular disease without an effective pharmaceutical treatment. Our study shows that age-associated SIRT1 reduction in VSMCs accelerates the formation and rupture of AAAs, whereas VSMC-specific overexpression of SIRT1 suppresses AAA formation and progression. SIRT1-mediated inhibition of vascular cell senescence suppresses vascular inflammation in AAAs. These findings suggest that the manipulation of SIRT1 activation may effectively inhibit vascular cell senescence, vascular inflammation, and delay or prevent AAA initiation and progression.
