CETP Protein Truncating Variants and Risk for CHD
Nomura et al. page 81

On the Cover: The cover image shows an almost confluent carpet of neutrophils in an en face view of the intimal surface of a mouse carotid artery with a neointima tailored to recapitulate features associated with human coronary arterial lesions, in a region of disturbed flow produced by a constrictive adventitial cuff. Note the multilobed nuclei characteristic of polymorphonuclear leukocytes. Green Ly6G+ fluorescence decorates the surface of these granulocytes. The article within provides evidence that such recruited neutrophils promote and amplify intimal injury and endothelial dysfunctions implicated in superficial erosion, a cause of arterial thrombosis poorly understood mechanistically. See related article, page 31.

In May 2017, the average time from submission to first decision for all original research papers submitted to Circulation Research was 12.3 days.
