Effect of Insulin in the Induction and Regression of Atherosclerosis in the Chick

By Jeremiah Stamler, M.D., Ruth Pick, M.D., and Louis N. Katz, M.D.

During the last 3 decades—the insulin era in the treatment of diabetes mellitus—atherosclerotic vascular complications have become the major causes of morbidity and mortality in diabetic persons, doubtless due, in part, to their increased life span with insulin therapy. Diabetics, as a group, undoubtedly have an increased susceptibility to atherosclerotic disease.1,2 The causative and pathogenetic factors responsible for this phenomenon remain obscure.

In view of this problem, experiments were undertaken to explore the effects of exogenous insulin on coronary and aorta atherogenesis in intact chicks.

Methods

Twelve series of chronic experiments, utilizing a total of 401 cockerels, were accomplished over a 5-year period (1954 to 1959). The established control techniques of this department for experimentation on atherosclerosis were employed throughout.1 Over-all, 3 different types of experiments were done to assess the influences of exogenous insulin: (1) regression or “unloading” experiments, in which birds were first fed an atherogenic diet for several weeks (mash + cholesterol + oil), then transferred to plain mash for 2 weeks, with administration of insulin during this regression period (tables 1 and 2); (2) “loading” experiments, in which birds were fed mash + cholesterol + oil, and simultaneously given insulin (table 3); (3) experiments on the effects of insulin on estrogen antiatherogenesis, in which chicks fed an atherogenic diet were simultaneously given estrogen and insulin (table 3).7,8

In accordance with established procedure,1 a record of feed intake and rate of weight gain was maintained in all experiments. Since groups receiving insulin exhibited decreased feed intake and rate of weight gain, paired-feeding methods were used to assess the possible role of these nonspecific effects in accounting for changes observed with insulin.9,10

Blood glucose concentration was measured as an index of insulin effect.

Results

In control birds, transferred from an atherogenic diet to plain mash for a terminal 2-week period, significant regression of coronary atherosclerosis occurred, in accordance with previous observations, while aortic lesions showed no change during this short period.8,11 In contrast, cockerels given insulin during this period exhibited no regression of lesions (table 1). This marked, significant difference between the 2 groups prevailed, although their patterns of cholesterolemia and phospholipemia were very similar, i.e., both exhibited a decline during these terminal 2 weeks from hyperlipemic to virtually normolipemic levels.

The control and insulin groups differed significantly in feed intake, weight and blood glucose level during these 2 weeks. The insulin-treated group had sustained periods of hypoglycemia, ate much less, and lost (rather than gained) weight (table 1).

Since previous work had shown that undernutrition inhibited regression of atherosclerosis,9,10 further pair-feeding experiments were undertaken to assess the role of this variable (table 2). The data of this experiment demonstrated that the insulin administration—and not matched underfeeding alone—was associated with complete inhibition of regression of coronary lesions. Thus, this phenomenon in birds receiving insulin cannot be attributed to the accompanying low feed intake, i.e., it is not basically an undernutrition effect.

In experiments on the effects of insulin on cholesterol-oil fed and estrogen-treated birds, no consistent influences of the islet hormone were noted. In 4 of the 9 series of experiments,

§Standard error of the mean.
†C-0 is mash + cholesterol + 5% cottonseed oil; the percent of cholesterol was 2, 2, 9, and 2% in series 33, 38, 48, and 57, respectively.
‡C-0 RM is mash + cholesterol + oil for 5 weeks, then plain mash for the terminal 2 weeks. Birds were 12, 12, 9, and 8 weeks of age at the beginning of the experiment in series 33, 38, 48, and 57, respectively.
§§Feed intake and Δ weight during terminal 2 weeks of experiment, on EM.
Glucose data collected on series 48 and 57 birds only; Somogyi method.
**Schoenheimer-Sperry method.
††C/P Ratio is the ratio of plasma total cholesterol to total phospholipids.
†††Glucose values 3 hours after injecting 10 units Lente insulin; glucose values at 6, 18, and 24 hours were 64±14, 151±63, and 202±18 mg. %, respectively.
§§§Per cent involvement is an estimate of severity of coronary atherosclerosis; it is a count of coronary vessels exhibiting atherosclerosis on microscopic examination, in relation to the total number of vessels visualized in standardized sudan IV-hematoxylin stained sections. The figure given represents involvement of vessel in birds with lesions. Negative birds are not included.
††††10 units of Lente insulin daily per bird.

Discussion

These experiments are supplementary to previous studies in this department on peroxisome proliferator effects of lipotropic factors, such as thiamin, niacin, vitamin B6, and lecithin. They also demonstrated that pancreatic hormone, they further showed that cholesterol fed to chicks raised in cholesterol and atherogenesis birds fed a diet rich in cholesterol and atherogenesis, and atherogenesis in birds fed a diet rich in cholesterol and atherogenesis, and atherogenesis. It is evident in the present series of experiments that insulin in large, hyperglycemic-inducing doses inhibits cholesterol absorption. Insulin's ability to induce atherosclerosis is not affected by the administration of diet-induced cholesterol or by the administration of insulin, without the administration of diet-induced cholesterol. The administration of insulin without the administration of diet-induced cholesterol did not affect significantly suppressed results were inconsistent, being negative in the other series. Analysis of the over-all data revealed that the 3 groups-esterone + insulin-did not differ significantly from controls.

Insulin and Atherosclerosis data were obtained, suggesting that insulin suppressed atherosclerosis in the coronary bed (series 33, 41, 45, 63). However, results were inconsistent, being negative in the other series. Analysis of the over-all data revealed that the 3 groups-esterone + insulin-did not differ significantly from controls.

Acknowledgment

We gratefully acknowledge the generous supply of cottonseed oil made available by Mr. M. Di Stone, Procter and Gamble Company, Chicago, Ill., and of cholesterol by Dr. N. S. Bitter of Merck and Company. Dr. W. R. Kirtley, of the Lilly Research Laboratory, kindly made available the insulin used in these experiments. Dr. J. B. Jewell, Ayerst Laboratories, generously supplied Premarin. It is a pleasure to acknowledge the contribution of the technical members of the Atherosclerosis Research Team: Miss C. Kakita, Mrs. Eva Miller, Mrs. Charlene Thompson, Mrs. Enid Whitaker, Mrs. Dorothy Unruh, Mrs. Mildred Travellers, Mrs. Montez Yankinscott, and Mr. Grady Crowley.

Summary

Insulin administration to intact cockerels made atherosclerotic by the feeding of a cholesterol-oil-containing diet prevented regression of coronary atherosclerosis. In some experiments, insulin slightly inhibited estrogen-induced protection of the coronary arteries when the birds were on a high cholesterol-oil diet.

*Three hours after injection of Lente insulin, 10 units. Hypoglycemia was also noted in both insulin-treated groups 1, 4, and 6 hours. Blood glucose values were at normal levels. For further explanation, see table 1.

Summary in Interlingua

Le administration de insuline a intacte gallotex que havera esite rendite atherosclerosi per un dieta a contento de cholesterol e olo prevenia le regression de atherosclerosis coronari. Le administration de insulina durante le induction de atherosclerosis havera nullo effetto super le diavloppoamento del lesionis. In plupro experimentis, insulina inhibiva levemente le protection estrogenogene del arterias coronari durante que le aves receiveva un dieta ric in cholesterol e olo.
