Targeted Disruption of Kir2.1 and Kir2.2 Genes Reveals the Essential Role of the Inwardly Rectifying K⁺ Current in K⁺-Mediated Vasodilation

Joshua J. Zaritsky, Delrae M. Eckman, George C. Wellman, Mark T. Nelson, Thomas L. Schwarz

Abstract—The molecular bases of inwardly rectifying K⁺ (Kir) currents and K⁺-induced dilations were examined in cerebral arteries of mice that lack the Kir2.1 and Kir2.2 genes. The complete absence of the open reading frame in animals homozygous for the targeted allele was confirmed. Kir2.1⁻/⁻ animals die 8 to 12 hours after birth, apparently due to a complete cleft of the secondary palate. In contrast, Kir2.2⁻/⁻ animals are viable and fertile. Kir currents were observed in cerebral artery myocytes isolated from control neonatal animals but were absent in myocytes from Kir2.1⁻/⁻ animals. Voltage-dependent K⁺ currents were similar in cells from neonatal control and Kir2.1⁻/⁻ animals. An increase in the extracellular K⁺ concentration from 6 to 15 mmol/L caused Ba²⁺-sensitive dilations in pressurized cerebral arteries from control and Kir2.2 mice. In contrast, arteries from Kir2.1⁻/⁻ animals did not dilate when the extracellular K⁺ concentration was increased to 15 mmol/L. In summary, Kir2.1 gene expression in arterial smooth muscle is required for Kir currents and K⁺-induced dilations in cerebral arteries. (Circ Res. 2000;87:160-166.)

Key Words: arteries | vasodilation | potassium channels | muscle, smooth | Kir2.1 channel

Local blood flow in the brain is matched to the metabolic needs of nearby neurons. Recent advances in imaging brain activity have taken advantage of this relationship between neuronal activity and local blood supply to map functional organization within the brain.¹ Potential metabolic signals to the cerebral vasculature include carbon dioxide, lactic acid, adenosine, H⁺, and histamine. However, a potent signal that has often been overlooked is an increase in extracellular potassium ions. During periods of cerebral hypoxia, ischemia, or hypoglycemia, extracellular K⁺ concentration ([K⁺]o) can rise to 10 to 16 mmol/L.² Increases in [K⁺]o presumably stimulates the electrogenic Na⁺,K⁺-ATPase,³ which causes a transient membrane potential hyperpolarization; this decays as Na⁺ is extruded.

The elevation of [K⁺]o also activates Kir channels and thereby causes membrane hyperpolarization toward the potassium equilibrium potential (EK). The membrane potential of myocytes in pressurized arteries is ~40 mV positive to EK. Therefore, increased Kir channel activity in 15 mmol/L [K⁺]o would cause a sustained hyperpolarization.⁴,⁵ Kir currents have been characterized in intact voltage-clamped cerebral arterioles⁶ and isolated arterial myocytes.⁷ Native Kir channels in arterial smooth muscle and cloned Kir2 family members show strong inward rectification, a conductance dependent on [K⁺]o, and a similar voltage- and time-dependent gating process.⁷,¹¹ Recently, Bradley et al.¹² identified transcripts for Kir2.1, but not Kir2.2 or Kir2.3, in isolated smooth myocytes from rat cerebral, coronary, and mesenteric arteries and showed that the cloned Kir2.1 currents most closely resemble those of the native current.

To explore the functional role of Kir2.1 and Kir2.2 in the cerebral vasculature, we engineered mice that lack these channels. This strategy permits the study of the effects of the deletion of a single Kir gene on the ionic currents of individual arterial myocytes and the contribution of that gene to K⁺-induced vasodilation. We demonstrate the absence of K⁺ currents in myocytes isolated from cerebral arteries of...
Kir2.1−/− mice but not from control animals. Cerebral arteries from Kir2.1−/− mice fail to dilate in response to elevations of [K+]o, from 6 to 15 mmol/L. In contrast, control and Kir2.2−/− arteries dilated normally. These results provide compelling evidence for the involvement of the inward rectifier potassium channel, Kir2.1, in potassium-induced dilations of cerebral arteries.

Materials and Methods

Generation of Targeted Mice

Mapped 129S/v genomic plasmids were graciously provided by Drs J.B. Redell and Bruce Tempel (University of Washington). The Kir2.2 gene was isolated from a 129S/v mouse genomic library. The 5′ arm of the Kir2.1 targeting construct was a ~5.2-kb SacI fragment of the genomic clone upstream of the Kir2.1 open reading frame. A 3.5-kb PstI fragment downstream of the cDNA coding sequence was used for the 3′ arm (Figure 1A). For Kir2.2, a 2.5-kb NolI-BamHI fragment 900 bases上游的 Kir2.2 open reading frame formed the 5′ arm, whereas the 3′ arm was a 7.2-kb StuI-SmaI downstream fragment (Figure 1B). In both constructs, the neomycin resistance gene was interposed between the 2 arms and a thymidine kinase cassette was added 3′.

These constructs were electroporated into R1 ES cells (courtesy of Andras Nagy, Mount Sinai Hospital, Toronto, Canada) and selected with 200 μg/ml G418 and 2 μmol/L gancyclovir. Colonies with homologous recombination events were determined with DNA hybridization. DNA from Kir2.1-targeted cells was digested with AflIII and probed with a 2.2-kb fragment 3′ to the targeting vector (Figure 1A). DNA from Kir2.2-targeted cells was digested with BamHI and probed with a 0.9-kb fragment 3′ to the Kir2.2 targeting vector (Figure 1B).

Mice that lack Kir2.1 were created through blastocyst injection (University of Cincinnati), and germ line transmission was confirmed. Kir2.2 mice were generated through aggregation with morulae from CD-1 mice.

Physiological Studies

Kir2.1−/− or control littermate mice (<1 day postnatal) were euthanized through exsanguination under deep pentobarbital anesthesia (150 mg/kg i.p.). Basilar, cerebellar, and posterior cerebral arteries were dissected in cold (4°C) oxygenated (95% O2 /5% CO2) PSS of 140 mmol/L. For diameter measurements, artery segments were cannulated and pressurized on glass pipettes mounted in a 5-ml chamber continuously superfused with aerated PSS at 37°C and pH 7.4. Arterial diameter was measured with video edge detection equipment (see online Materials and Methods for additional details; available at http://www.circresaha.org).

K+ currents in enzymatically isolated myocytes were measured using the conventional whole-cell configuration of the patch-clamp technique. Patch pipettes contained (in mmol/L) K-aspartate 87, KCl 20, CaCl2 1, MgCl2 1, HEPES 10, EGTA 10, and KOH 25 (pH 7.2). Seals were made in an extracellular solution containing (in mmol/L) NaCl 134, KCl 6, MgCl2 1, CaCl2 0.1, glucose 10, and HEPES 10 (pH 7.4). To maximize Kir currents, [K+]o, was increased to 140 mmol/L.

Data are expressed as mean±SEM. Statistical significance (P<0.05) was assessed with Student’s paired or unpaired t test as appropriate.

An expanded Materials and Methods section is available online at http://www.circresaha.org.
DNA analysis confirmed the absence of the Kir2.2 open reading frame in animals homozygous for the targeted allele (Figure 1C). In contrast to Kir2.1/2 mice, Kir2.2/2 mice appear normal as adults. A histological analysis of their hearts and brains revealed no abnormalities.

**Inward Rectifier Currents Are Absent in Cerebral Artery Myocytes Isolated From Kir2.1/2 Mice**

To explore the role of Kir2.1 channels, K^+ currents were measured in isolated myocytes from cerebral arteries of control (wild type and heterozygous littermates) and Kir2.1/2 mice. The control and Kir2.1/2 myocytes were similar in size, based on cell capacitance (control 5.5 ± 0.3 pF, n = 25; Kir2.1/2: 5.7 ± 0.6 pF, n = 23) but smaller than myocytes isolated from similar arteries of adult mice (12.1 ± 0.8 pF, n = 5).

Ba^{2+}-sensitive inward K^+ currents in 140 mmol/L [K^+]_o were evoked with voltage ramps from −100 to +40 mV at 0.3 mV/ms (Figure 3A). Myocytes from control arteries exhibited significant inward currents negative to the potassium equilibrium potential (−0 mV). Current density (−8.7 ± 2.8 pA/pF at −100 mV, n = 9) was similar to previous measurements made with adult rat cerebral myocytes (−8 pA/pF). In contrast, inward currents were not detected in Kir2.1/2 myocytes (−0.4 ± 0.2 pA/pF at −100 mV, n = 9, significantly different from control, P < 0.01) (Figures 3A and 3B).

To determine whether other K^+ currents were affected by ablation of the Kir2.1 gene, voltage-dependent K^+ currents were examined. Currents in 6 mmol/L [K^+]_o were elicited by a series of 10-mV depolarizing steps (−60 to +50 mV) from a holding potential of −70 mV (Figures 4A and 4B). Steady-state currents were measured at the end of the 1.5-second voltage step and were plotted, normalized to cell capacitance, as a function of the depolarizing voltage (Figure 4C). In marked contrast to the absence of Kir currents, there were no significant differences in the outward current ampli-
Figure 3. Kir channel currents are absent in myocytes isolated from cerebral arteries of neonatal Kir2.1−/− mice. A, Current-voltage relationship of Kir measured as a Ba2+-sensitive current in cerebral artery myocytes from representative control and Kir2.1−/− animals. Currents were obtained during voltage ramps from −100 to +40 mV at 0.3 mV/ms in symmetrical 140 mmol/L K+ in the presence and absence of 100 μmol/L Ba2+. B, Summary of 100 μmol/L Ba2+-sensitive current at −100 mV obtained from control (n=9 cells) and Kir2.1−/− (n=9) myocytes (P<0.01).

Elevations in [K+]o Dilated Control but Not Kir2.1−/− Arteries

The neonatal lethality of the Kir2.1−/− mice required that techniques for the analysis of vascular reactivity be adapted to newborn mouse pups. Neonatal arteries were delicate, and sometimes both Kir2.1−/− and control animals evinced spontaneous fluctuations in diameter. Neonatal control arteries constricted to the thromboxane A2 mimetic U46619 (0.1 to 0.3 μmol/L): arterial diameter decreased from 115.3±11.3 to 65.3±5.3 μm (n=3). This constriction provided a background on which the effects of vasodilatory agents could be examined. Forskolin (1 μmol/L), an activator of adenylate cyclase, dilated cerebral arteries from neonatal controls, reversing by 43.7±15.0% (n=3) the constricitions observed in the presence of U46619.

U46619 also constricted cerebral arteries isolated from Kir2.1−/− neonatal mice from 105.0±12.4 to 70.7±9.7 μm (n=4). Forskolin at 1 μmol/L also dilated Kir2.1−/− arteries, reversing 47.0±21.8% (n=3) of the constriction to U46619. Elevation of [K+]o, from 6 to 15 mmol/L dilated U46619-constricted arteries from control mice by 71.5±3.1% (n=3) (Figures 5A and 5C). In marked contrast, elevations of [K+]o did not alter the diameter of arteries from Kir2.1−/− mice (Figures 5B and 5C), indicating a role of Kir2.1 channels in K+-induced dilations.

To further investigate the role of Kir 2.1 channels, the effects of [K+]o on pressure-induced constrictions were examined. Pressure-induced constriction (“myogenic tone”) is a major contributor to vascular resistance and the regulation of blood flow in vivo.7 Cerebral arteries from neonatal control and Kir2.1−/− mice also exhibit pressure-induced constrictions. The elevation of intravascular pressure to 40 mm Hg constricted cerebral arteries by 24.8±3.7% (n=5) in control mice and 26.8±3.8% (n=8) in Kir2.1−/− mice. The passive diameters, obtained in the presence of Ca2+-free PSS and 1 μmol/L nisoldipine, of control (95.8±12.5 μm) and Kir2.1−/− (88.6±9.1 μm) cerebral arteries were not significantly different at an intravascular pressure of 40 mm Hg.
Figure 6. Elevation of [K\(^+\)]\(\text{m}\) dilates pressurized neonatal cerebral arteries in control but not Kir2.1\(-/-\) mice. Diameter records from control (A and C) and Kir2.1\(-/-\) (B and D) cerebral artery segments constricted by increased intravascular pressure to 40 mm Hg. Both elevated K\(^+\) (A) and 1 \(\mu\)mol/L forskolin (C) dilate control arteries. Kir2.1\(-/-\) arteries failed to dilate in response to elevation of K\(^+\) (B) while retaining their responsiveness to forskolin (D). E. Summary of percent dilation to 15 mmol/L external K\(^+\) (n=5 control, n=7 Kir2.1\(-/-\)) or 1 \(\mu\)mol/L forskolin (n=3 control, n=6 Kir2.1\(-/-\)). Ba\(^2+\) (100 \(\mu\)mol/L) inhibited K\(^+\)-induced dilations in cerebral arteries from control mice (n=5). *P<0.05.

The responses of pressurized cerebral arteries from control and Kir2.1\(-/-\) mice to elevated [K\(^+\)]\(\text{m}\) differed significantly from each other, which is consistent with observations in U46619-constricted arteries. Control pressurized arteries dilated to an increase in [K\(^+\)]\(\text{m}\) from 6 to 15 mmol/L (Figures 6A and 6E), reversing 52.8\(\pm\)7.8% (n=5) of the pressure-induced constriction. The addition of a blocker of Kir channels, BaCl\(_2\) (50 \(\mu\)mol/L), had no significant effect on diameter in 6 mmol/L K\(^+\) but prevented K\(^+\)-induced dilations (Figure 6E). In contrast, pressurized Kir2.1\(-/-\) vessels did not dilate to 15 mmol/L [K\(^+\)]\(\text{m}\) (Figures 6B and 6E). The failure of pressurized Kir2.1\(-/-\) arteries to dilate in response to [K\(^+\)]\(\text{m}\), did not correspond to a general loss of reactivity. Forskolin (1 \(\mu\)mol/L) reversed pressure-induced constrictions in both control and Kir2.1\(-/-\) cerebral arteries (percent dilations: control 96.3\(\pm\)1.9%, n=3; control: Kir2.1\(-/-\) 77.3\(\pm\)6.9%, n=6) (Figures 6C through 6E).

Elevations in [K\(^+\)]\(\text{m}\), Dilated Pressurized Cerebral Arteries From Control and Kir 2.2\(-/-\) Mice

To assess a possible role of Kir2.2 channels in the mouse vasculature, cerebral artery diameter was examined in Kir2.2\(-/-\) adult mice and their wild-type littermates or age-matched FVB mice. Cerebral arteries from control and Kir2.2\(-/-\) mice constricted to the same degree to intravascular pressure. At 80 mm Hg, control arteries constricted from 146.6\(\pm\)8.9 to 117.0\(\pm\)6.2 \(\mu\)m (n=7), and Kir2.2\(-/-\) arteries constricted from 143.2\(\pm\)13.1 to 117.9\(\pm\)11.1 \(\mu\)m (n=7). In contrast to the results with Kir2.1\(-/-\) arteries, increased [K\(^+\)]\(\text{m}\) from 6 to 15 mmol/L caused similar dilations of cerebral arteries from control (46.3\(\pm\)5.4%, n=7) and Kir 2.2\(-/-\) mice (42.5\(\pm\)4.9%, n=7) (Figure 7).

**Discussion**

We explored the role of Kir2.1 in giving rise to Kir currents and in mediating K\(^+\)-induced dilations of cerebral arteries by studying lines of mice in which the genes that encode Kir2.1 or Kir2.2 have been removed. In neonatal cerebral arteries, the Kir2.1 gene proved essential for the inward rectifier current and for vasodilation in response to elevated [K\(^+\)]. These findings are consistent with a causal relationship between Kir and K\(^+\)-induced vasodilation. The Kir2.1 and Kir2.2 knockout mice have also provided an opportunity to study the roles that Kir2.1 and Kir2.2 play in the heart (J.J. Zaritsky and T.L. Schwarz, unpublished data, 1999). In the future, these mice should enable an examination of Kir2.1 and Kir2.2 in other tissues in which either channel is found, such as skeletal muscle, smooth muscle of the gastrointestinal tract, macrophages, and the central nervous system.

**Cleft Plate Phenotype of Kir2.1\(-/-\) Mice**

The perinatal lethality of the Kir2.1 knockouts could derive from a defect in any of the organ systems that express this channel. However, because these animals do not evince arrhythmias or skeletal paralysis and because the appearance of the animals indicates dehydration and respiratory problems, the lethality is most likely the result of the cleft palate. The presence of a cleft palate in 100% of the Kir2.1\(-/-\) animals suggests intriguing possible roles for the Kir2.1 protein. Although cleft palates can be associated with other...
craniofacial defects and cardiac malformations,\textsuperscript{13} in the Kir2.1 knockout animals, other facial midline structures appear normal and no defects in cardiac anatomy were detected.

A variety of cell signaling, proliferation, and differentiation steps are involved in palate development, and a defect in any of them can result in a cleft palate.\textsuperscript{13} One possibility is that Kir2.1 provides a driving force for Ca\textsuperscript{2+} entry in the developing palate by maintaining a relatively hyperpolarized membrane potential and thereby permits critical developmental signals. Alternatively, however, the action of the channel could lie elsewhere, including in the nervous system or skeletal muscle of the tongue, because mislocalization of the tongue can prevent the palatal buds from making contact with each other at the midline.\textsuperscript{13}

**Role of Kir2.1 Channels in Cerebral Artery Smooth Muscle**

Despite the early death of Kir2.1\textsuperscript{−/−} pups, we were able to examine K\textsuperscript{+} currents from isolated arterial myocytes. Although Kir currents from control myocytes were similar to those observed in previous studies of adult myocytes, they were notably absent in myocytes from Kir2.1\textsuperscript{−/−} animals. Voltage-dependent K\textsuperscript{+} currents in Kir2.1\textsuperscript{−/−} myocytes appeared unaffected, indicating that the ablation of the Kir2.1 gene had no secondary effect on voltage-dependent K\textsuperscript{+} channels. Thus, the Kir2.1 gene is necessary for the Kir currents in cerebral arteries. This result is consistent with earlier reports that the native Kir current in arterial myocytes had biophysical and pharmacological properties similar to the cloned Kir2.1 channel.\textsuperscript{5,7,11,12} We cannot exclude the possibility that another subunit coassembles with Kir2.1 to form the channel pore.\textsuperscript{14} The elevation of K\textsubscript{1}o to 15 mmol/L shifts E\textsubscript{K} from −60 mV to −45 mV to −60 mV.\textsuperscript{5} This hyperpolarization decreases the open probability of voltage-activated Ca\textsuperscript{2+} channels and thereby reduces cytosolic Ca\textsuperscript{2+} levels and vascular tone.\textsuperscript{8}

Despite the short lifespan of the Kir2.1\textsuperscript{−/−} mice, we were able to use cerebral arteries from these animals to probe the role of Kir. Consistent with a causal relationship between Kir and K\textsuperscript{+}-induced dilations, elevations in [K\textsuperscript{+}], did not dilate cerebral arteries from Kir2.1\textsuperscript{−/−} animals, although neonatal arteries from control mice did dilate. The arteries in the mutants remained responsive to forskolin and to changes in Ca\textsuperscript{2+} influx. Thus, although other vasodilatory mechanisms remained intact, the removal of the Kir2.1 gene and inwardly rectifying currents resulted in the selective absence of K\textsuperscript{+}-induced vasodilation.

In contrast, experiments that compared arteries from Kir2.2 knockout with control arteries failed to identify any differences. Both sets of adult vessels exhibited similar pressure-induced constrictions and both dilated when exposed to an external solution that contained 15 mmol/L K\textsuperscript{+} or to 0 mmol/L Ca\textsuperscript{2+}. Thus, it is unlikely that the Kir2.2 gene plays a role similar to that of Kir2.1 in the regulation of vascular tone.

The alternative mechanism that had been proposed to account for K\textsuperscript{+}-induced vasodilation suggested that modest increases in [K\textsuperscript{+}o], would increase the electrogenic Na\textsuperscript{+},K\textsuperscript{+}-ATPase activity, causing hyperpolarization.\textsuperscript{9,10} However, previous studies had shown that the inhibition of the Na\textsuperscript{+},K\textsuperscript{+}-ATPase with ouabain or dihydro-ouabain did not prevent dilations in response to increased [K\textsuperscript{+}], >5 mmol/L.\textsuperscript{5,10} The present study strengthens the argument that the Na\textsuperscript{+},K\textsuperscript{+}-ATPase does not play a major role in the vasodilation caused by increasing [K\textsuperscript{+}], from 6 to 15 mmol/L, because no residual dilatory mechanism was detected once the inward rectifier current had been removed. Thus, the Na\textsuperscript{+},K\textsuperscript{+}-ATPase alone was not sufficient for K\textsuperscript{+}-induced dilations in these conditions. However, we cannot rule out the possibility that transient changes in Na\textsuperscript{+},K\textsuperscript{+}-ATPase activity contribute to the regulation of cerebral artery diameter in response to changes in [K\textsuperscript{+}], <5 mmol/L.

The availability of a knockout mouse that lacks K\textsuperscript{+}-dependent vasodilation will permit the examination of the role of K\textsuperscript{+} as a messenger for the homeostatic regulation of blood flow in active tissue. Elevations in [K\textsuperscript{+}], in the range used in the present study have been observed in the brain and myocardium.\textsuperscript{2,4,15} These observations, combined with the ability of K\textsuperscript{+} to dilate blood vessels, make K\textsuperscript{+} an attractive candidate messenger to communicate the local state of activity to blood vessels.
